D. Normal Mixture Models and Elliptical Models

1. Normal Variance Mixtures

2. Normal Mean-Variance Mixtures

3. Spherical Distributions

4. Elliptical Distributions
D1. Multivariate Normal Mixture Distributions

Pros of Multivariate Normal Distribution

• inference is “well known” and estimation is “easy”.

• distribution is given by $\mu$ and $\Sigma$.

• linear combinations are normal ($\rightarrow$ VaR and ES calcs easy).

• conditional distributions are normal.

• For $(X_1, X_2) \sim N_2(\mu, \Sigma)$,

$$\rho(X_1, X_2) = 0 \iff X_1 \text{ and } X_2 \text{ are independent.}$$
Multivariate Normal Variance Mixtures

Cons of Multivariate Normal Distribution

• tails are thin, meaning that extreme values are scarce in the normal model.

• joint extremes in the multivariate model are also too scarce.

• the distribution has a strong form of symmetry, called elliptical symmetry.

How to repair the drawbacks of the multivariate normal model?
Multivariate Normal Variance Mixtures

The random vector $\mathbf{X}$ has a (multivariate) normal variance mixture distribution if

$$\mathbf{X} \overset{d}{=} \mathbf{\mu} + \sqrt{W} \mathbf{AZ},$$

where

- $\mathbf{Z} \sim N_k(0, I_k)$;
- $W \geq 0$ is a scalar random variable which is independent of $\mathbf{Z}$; and
- $A \in \mathbb{R}^{d \times k}$ and $\mathbf{\mu} \in \mathbb{R}^d$ are a matrix and a vector of constants, respectively.

Set $\Sigma := AA^\top$. Observe: $\mathbf{X}|W = w \sim N_d(\mathbf{\mu}, w\Sigma)$. 
Multivariate Normal Variance Mixtures

Assumption: \( \text{rank}(A) = d \leq k \), so \( \Sigma \) is a positive definite matrix.

If \( E(W) < \infty \) then easy calculations give

\[
E(X) = \mu \quad \text{and} \quad \text{cov}(X) = E(W)\Sigma.
\]

We call \( \mu \) the location vector or mean vector and we call \( \Sigma \) the dispersion matrix.

The correlation matrices of \( X \) and \( AZ \) are identical:

\[
\text{corr}(X) = \text{corr}(AZ).
\]

Multivariate normal variance mixtures provide the most useful examples of elliptical distributions.
Properties of Multivariate Normal Variance Mixtures

1. Characteristic function of multivariate normal variance mixtures

\[
\phi_X(t) = E\left(\exp\{it^\top X\}\right) = E\left(E\left(\exp\{it^\top X\}|W\right)\right) = E\left(\exp\{it^\top \mu - \frac{1}{2}Wt^\top \Sigma t\}\right).
\]

Denote by \(H\) the d.f. of \(W\). Define the Laplace-Stieltjes transform of \(H\)

\[
\hat{H}(\theta) := E(e^{-\theta W}) = \int_0^\infty e^{-\theta u} dH(u).
\]

Then

\[
\phi_X(t) = \exp\{it^\top \mu\} \hat{H}\left(\frac{1}{2}t^\top \Sigma t\right).
\]

Based on this, we use the notation \(X \sim M_d(\mu, \Sigma, \hat{H})\).
Properties of Multivariate Normal Variance Mixtures

2. Linear operations. For \( \mathbf{X} \sim M_d(\mu, \Sigma, \hat{H}) \) and \( \mathbf{Y} = B\mathbf{X} + \mathbf{b} \), where \( B \in \mathbb{R}^{k \times d} \) and \( \mathbf{b} \in \mathbb{R}^k \), we have

\[
\mathbf{Y} \sim M_k(B\mu + \mathbf{b}, B\Sigma B^\top, \hat{H}).
\]

As a special case, if \( \mathbf{a} \in \mathbb{R}^d \),

\[
\mathbf{a}^\top \mathbf{X} \sim M_1(a^\top \mu, a^\top \Sigma a, \hat{H}).
\]

Proof:

\[
\phi_{\mathbf{Y}}(\mathbf{t}) = E \left( e^{i\mathbf{t}^\top (B\mathbf{X} + \mathbf{b})} \right) = e^{i\mathbf{t}^\top \mathbf{b}} \phi_{\mathbf{X}}(B^\top \mathbf{t})
= e^{i\mathbf{t}^\top (\mathbf{b} + B\mu)} \hat{H} \left( \frac{1}{2} \mathbf{t}^\top B\Sigma B^\top \mathbf{t} \right).
\]
Properties of Multivariate Normal Variance Mixtures

3. Density. If $P[W = 0] = 0$ then as $X|W = w \sim N_d(\mu, w\Sigma)$,

$$f_X(x) = \int_0^\infty f_{X|W}(x|w) dH(w)$$

$$= \int_0^\infty \frac{w^{-d/2}}{(2\pi)^{d/2}|\Sigma|^{1/2}} \exp \left\{ - \frac{(x - \mu)^\top \Sigma^{-1}(x - \mu)}{2w} \right\} dH(w).$$

The density depends on $x$ only through $(x - \mu)^\top \Sigma^{-1}(x - \mu)$. 
4. Independence.

If $\Sigma$ is diagonal, then the components of $X$ are \textit{uncorrelated}.

But, in general, they are not independent,
e.g. for $X \sim M_2(\mu, I_2, \hat{H})$,

$$\rho(X_1, X_2) = 0 \not\Rightarrow X_1 \text{ and } X_2 \text{ are independent.}$$

Indeed, $X_1$ and $X_2$ are independent iff $W$ is a.s. constant.
i.e. when $X = (X_1, X_2)^\top$ is multivariate normally distributed.
Examples of Multivariate Normal Variance Mixtures

Two point mixture

\[ W = \begin{cases} 
  k_1 \text{ with probability } p, \\
  k_2 \text{ with probability } 1 - p \end{cases} \quad k_1, k_2 > 0, k_1 \neq k_2. \]

Could be used to model two regimes - ordinary and stress.

Multivariate t

\( W \) has an inverse gamma distribution, \( W \sim \text{Ig}(\nu/2, \nu/2) \).

Equivalently, \( \frac{\nu}{W} \sim \chi_\nu^2 \).

This gives multivariate t with \( \nu \) degrees of freedom.

Symmetric generalised hyperbolic

\( W \) has a GIG (generalised inverse Gaussian) distribution.
The Multivariate t Distribution

Density of multivariate t

\[
f(x) = k_{\Sigma, \nu, d} \left( 1 + \frac{(x - \mu)' \Sigma^{-1} (x - \mu)}{\nu} \right)^{-\frac{(\nu + d)}{2}}
\]

where \( \mu \in \mathbb{R}^d \), \( \Sigma \in \mathbb{R}^{d \times d} \) is a positive definite matrix, \( \nu \) is the degrees of freedom and \( k_{\Sigma, \nu, d} \) is a normalizing constant.

- \( E(X) = \mu \).

- As \( E(W) = \frac{\nu}{\nu - 2} \), we get \( \text{cov}(X) = \frac{\nu}{\nu - 2} \Sigma \). For finite variances/correlations, \( \nu > 2 \).

Notation: \( X \sim t_d(\nu, \mu, \Sigma) \).
Left plot is bivariate normal, right plot is bivariate t with $\nu = 3$. Mean is zero, all variances equal 1 and $\rho = -0.7$. 

Bivariate Normal and t
Simulated data (2000) from models fitted by maximum likelihood to BMW-Siemens data. Left plot is fitted normal, right plot is fitted $t_3$. 
Simulating Normal Variance Mixture Distributions

To simulate $X \sim M_d(\mu, \Sigma, \hat{H})$.

1. Generate $Z \sim N_d(0, \Sigma)$, with $\Sigma = AA^\top$.

2. Generate $W$ with df $H$ (with Laplace-Stieltjes transform $\hat{H}$), independent of $Z$.

3. Set $X = \mu + \sqrt{W}AZ$. 
Simulating Normal Variance Mixture Distributions

Example: $t$ distribution

To simulate a vector $\mathbf{X} \sim t_d(\nu, \mu, \Sigma)$.

1. Generate $\mathbf{Z} \sim N_d(0, \Sigma)$, with $\Sigma = AA^\top$.

2. Generate $V \sim \chi^2_{\nu}$ and set $W = \frac{\nu}{V}$.

3. Set $\mathbf{X} = \mu + \sqrt{W} A \mathbf{Z}$. 
Symmetry in Normal Variance Mixture Distributions

Elliptical symmetry means 1-dimensional margins are symmetric.

Observation for stock returns: negative returns (losses) have heavier tails than positive returns (gains).

Introduce asymmetry by mixing normal distributions with different means as well as different variances.

This gives the class of multivariate normal mean-variance mixtures.
D2. Multivariate Normal Mean-Variance Mixtures

The random vector $\mathbf{X}$ has a (multivariate) normal mean-variance mixture distribution if

$$
\mathbf{X} \overset{d}{=} \mathbf{m}(W) + \sqrt{W} A \mathbf{Z},
$$

(2)

where

- $\mathbf{Z} \sim N_k(0, I_k)$;

- $W \geq 0$ is a scalar random variable which is independent of $\mathbf{Z}$; and

- $A \in \mathbb{R}^{d \times k}$ and $\mu \in \mathbb{R}^d$ are a matrix and a vector of constants, respectively.

- $\mathbf{m} : [0, \infty) \rightarrow \mathbb{R}^d$ is a measurable function.
Normal Mean-Variance Mixtures

Normal mean-variance mixture distributions add asymmetry.

In general, they are no longer elliptical and $\text{corr}(X) \neq \text{corr}(AZ)$.

Set $\Sigma := AA^\top$. Observe:

$$X|W = w \sim N_d(m(w), w\Sigma).$$

A concrete specification of $m(W)$ is $m(W) = \mu + W\gamma$.

Example: Let $W$ have generalized inverse Gaussian distribution to get $X$ generalised hyperbolic.

$\gamma = 0$ places us back in the (elliptical) normal variance mixture family.
D3. Spherical Distributions

Recall that a map $U \in \mathbb{R}^{d \times d}$ is orthogonal if $UU^\top = U^\top U = I_d$.

A random vector $\mathbf{Y} = (Y_1, \ldots, Y_d)^\top$ has a spherical distribution if for every orthogonal map $U \in \mathbb{R}^{d \times d}$

$$\mathbf{Y} \overset{d}{=} U\mathbf{Y}.$$ 

Use $\|\cdot\|$ to denote the Euclidean norm, i.e. for $\mathbf{t} \in \mathbb{R}^d$,

$$\|\mathbf{t}\| = (t_1^2 + \cdots + t_d^2)^{1/2}.$$
Spherical Distributions

THEOREM The following are equivalent.

1. \( \mathbf{Y} \) is spherical.

2. There exists a function \( \psi \) of a scalar variable such that

\[
\phi_\mathbf{Y}(\mathbf{t}) = E(e^{i\mathbf{t}^\top \mathbf{Y}}) = \psi(\|\mathbf{t}\|^2), \quad \forall \mathbf{t} \in \mathbb{R}^d.
\]

3. For every \( \mathbf{a} \in \mathbb{R}^d \),

\[
\mathbf{a}^\top \mathbf{Y} \overset{d}{=} \|\mathbf{a}\|_{\mathbf{Y}_1}.
\]

We call \( \psi \) the characteristic generator of the spherical distribution.

Notation: \( \mathbf{Y} \sim S_d(\psi) \).
Examples of Spherical Distributions

• \( \mathbf{X} \sim N_d(\mathbf{0}, I_d) \) is spherical. The characteristic function is

\[
\phi_{\mathbf{X}}(t) = E(e^{it^\top \mathbf{X}}) = \exp \left( -\frac{1}{2} t^\top t \right).
\]

Then \( \mathbf{X} \sim S_d(\psi) \) with \( \psi(t) = \exp \left( -\frac{1}{2} t \right) \).

• \( \mathbf{X} \sim M_d(\mathbf{0}, I_d, \hat{H}) \) is spherical, i.e. \( \mathbf{X} \overset{d}{=} \sqrt{\mathbf{W}} \mathbf{Z} \).

The characteristic function is

\[
\phi_{\mathbf{X}}(t) = \hat{H} \left( \frac{1}{2} t^\top t \right).
\]

Then \( \mathbf{X} \sim S_d(\psi) \) with \( \psi(t) = \hat{H}(\frac{1}{2} t) \).
D4. Elliptical distributions

A random vector \( \mathbf{X} = (X_1, \ldots, X_d)^\top \) is called elliptical if it is an affine transform of a spherical random vector \( \mathbf{Y} = (Y_1, \ldots, Y_k)^\top \), i.e.

\[
\mathbf{X} \overset{d}{=} \mu + A\mathbf{Y},
\]

where \( \mathbf{Y} \sim S_k(\psi) \) and \( A \in \mathbb{R}^{d \times k} \), \( \mu \in \mathbb{R}^d \) are a matrix and vector of constants, respectively.

Set \( \Sigma = AA^\top \).

Example: Multivariate normal variance mixture distributions
\[
\mathbf{X} \overset{d}{=} \mu + \sqrt{W}A\mathbf{Z}.
\]
Properties of Elliptical Distributions

1. Characteristic function of elliptical distributions

The characteristic function is

\[ \phi_X(t) = E(e^{it^\top X}) = E(e^{it^\top (\mu + AY)}) = e^{it^\top \mu} \psi(t^\top \Sigma t) \]

Notation: \( X \sim Ed(\mu, \Sigma, \psi) \).

We call \( \mu \) the location vector, \( \Sigma \) the dispersion matrix and \( \psi \) the characteristic generator.

Remark: \( \mu \) is unique but \( \Sigma \) and \( \psi \) are only unique up to a positive constant, since for any \( c > 0 \),

\[ X \sim Ed(\mu, \Sigma, \psi) \sim Ed\left(\mu, c\Sigma, \psi\left(\frac{\cdot}{c}\right)\right) \]
Properties of Elliptical Distributions

2. Linear operations. For $X \sim E_d(\mu, \Sigma, \psi)$ and $Y = BX + b$, where $B \in \mathbb{R}^{k \times d}$ and $b \in \mathbb{R}^k$, we have

$$Y \sim E_k(B\mu + b, B\Sigma B^\top, \psi).$$

As a special case, if $a \in \mathbb{R}^d$,

$$a^\top X \sim E_1(a^\top \mu, a^\top \Sigma a, \psi).$$

Proof:

$$\phi_Y(t) = E \left( e^{it^\top (BX+b)} \right) = e^{it^\top b} \phi_X(B^\top t) = e^{it^\top (b+B\mu)} \psi \left( t^\top B\Sigma B^\top t \right).$$
Properties of Elliptical Distributions

3. Marginal distributions. For $\mathbf{X} \sim E_d(\mu, \Sigma, \psi)$, set

$$\mathbf{X}_1 = (X_1, \ldots, X_k)\top$$

and

$$\mathbf{X}_2 = (X_{k+1}, \ldots, X_d)\top$$

$$\mu = \begin{pmatrix} \mu_1 \\ \mu_2 \end{pmatrix}$$

and

$$\Sigma = \begin{pmatrix} \Sigma_{11} & \Sigma_{12} \\ \Sigma_{21} & \Sigma_{22} \end{pmatrix}.$$ 

Then

$$\mathbf{X}_1 \sim E_k(\mu_1, \Sigma_{11}, \psi)$$

and

$$\mathbf{X}_2 \sim E_{d-k}(\mu_2, \Sigma_{22}, \psi).$$
Properties of Elliptical Distributions

4. Conditional distributions. The conditional distribution of $X_2 | X_1 = x_1$ is elliptical, but in general with a different characteristic generator $\tilde{\psi}$.

In the special case of multivariate normality, the characteristic generator remains the same.
5. Convolutions. Let $X$ and $Y$ be independent and

$$X \sim E_d(\mu, \Sigma, \psi) \quad Y \sim E_d(\tilde{\mu}, \tilde{\Sigma}, \tilde{\psi}).$$

If $\Sigma = \tilde{\Sigma}$ then

$$X + Y \sim E_d(\mu + \tilde{\mu}, \Sigma, \tilde{\psi}),$$

where $\tilde{\psi}(u) := \psi(u)\tilde{\psi}(u)$. 
Properties of Elliptical Distributions

• The density of an elliptical distribution is constant on ellipsoids.

• Many of the nice properties of the multivariate normal are preserved. In particular, all linear combinations $a_1 X_1 + \ldots + a_d X_d$ are of the same type.

• All marginal distributions are of the same type.

Two rvs $X$ and $Y$ (or their distributions) are of the same type if there exist constants $a > 0$ and $b \in \mathbb{R}$ such that $X \overset{d}{=} aY + b$.
