

# STRONG CONVERGENCE OF APPROXIMATION FIXED POINTS FOR NONEXPANSIVE NONSELF-MAPPING

RUDONG CHEN AND ZHICHUAN ZHU

*Received 17 May 2006; Accepted 22 June 2006*

Let  $C$  be a closed convex subset of a uniformly smooth Banach space  $E$ , and  $T : C \rightarrow E$  a nonexpansive nonself-mapping satisfying the weakly inwardness condition such that  $F(T) \neq \emptyset$ , and  $f : C \rightarrow C$  a fixed contractive mapping. For  $t \in (0, 1)$ , the implicit iterative sequence  $\{x_t\}$  is defined by  $x_t = P(tf(x_t) + (1-t)Tx_t)$ , the explicit iterative sequence  $\{x_n\}$  is given by  $x_{n+1} = P(\alpha_n f(x_n) + (1-\alpha_n)Tx_n)$ , where  $\alpha_n \in (0, 1)$  and  $P$  is a sunny nonexpansive retraction of  $E$  onto  $C$ . We prove that  $\{x_t\}$  strongly converges to a fixed point of  $T$  as  $t \rightarrow 0$ , and  $\{x_n\}$  strongly converges to a fixed point of  $T$  as  $\alpha_n$  satisfying appropriate conditions. The results presented extend and improve the corresponding results of Hong-Kun Xu (2004) and Yisheng Song and Rudong Chen (2006).

## 1. Introduction

Let  $C$  be a nonempty closed convex subset of a Banach space  $E$ , and Let  $T : C \rightarrow C$  be a nonexpansive mapping (i.e.,  $\|Tx - Ty\| \leq \|x - y\|$  for all  $x, y \in C$ ). We use  $\text{Fix}(T)$  to denote the set of fixed points of  $T$ ; that is,  $\text{Fix}(T) = \{x \in C : x = Tx\}$ . Recall that a self-mapping  $f : C \rightarrow C$  is a contraction on  $C$  if there exists a constant  $\beta \in (0, 1)$  such that

$$\|f(x) - f(y)\| \leq \beta \|x - y\|, \quad x, y \in C. \quad (1.1)$$

Xu (see [6]) defined the following two viscosity iterations for nonexpansive mappings:

$$x_t = tf(x_t) + (1-t)Tx_t, \quad x \in C, \quad (1.2)$$

$$x_{n+1} = \alpha_n f(x_n) + (1-\alpha_n)Tx_n, \quad (1.3)$$

where  $\alpha_n$  is a sequence in  $(0, 1)$ . Xu proved the strong convergence of  $\{x_t\}$  defined by (1.2) as  $t \rightarrow 0$  and  $\{x_n\}$  defined by (1.3) in both Hilbert space and uniformly smooth Banach space.

## 2 Strong convergence of approximation fixed points

Recently, Song and Chen [2] proved if  $C$  is a closed subset of a real reflexive Banach space  $E$  which admits a weakly sequentially continuous duality mapping from  $E$  to  $E^*$ , and if  $T : C \rightarrow E$  is a nonexpansive nonself-mapping satisfying the weakly inward condition,  $F(T) \neq \emptyset$ ,  $f : C \rightarrow C$  is a fixed contractive mapping, and  $P$  is a sunny nonexpansive retraction of  $E$  onto  $C$ , then the sequences  $\{x_t\}$  and  $\{x_n\}$  defined by

$$x_t = P(tf(x_t) + (1-t)Tx_t), \quad (1.4)$$

$$x_{n+1} = P(\alpha_n f(x_n) + (1-\alpha_n)Tx_n) \quad (1.5)$$

strongly converge to a fixed point of  $T$ .

In this paper, we establish the strong convergence of both  $\{x_t\}$  defined by (1.4) and  $\{x_n\}$  defined by (1.5) for a nonexpansive nonself-mapping  $T$  in a uniformly smooth Banach space. Our results extend and improve the results in [2, 6].

### 2. Preliminaries

Let  $E$  be a real Banach space and let  $J$  denote the normalized duality mapping from  $E$  into  $2^{E^*}$  given by

$$J(x) = \{f \in E^* : \langle x, f \rangle = \|x\| \|f\|, \|x\| = \|f\|\} \quad \forall x \in E, \quad (2.1)$$

where  $E^*$  denotes the dual space of  $E$  and  $\langle \cdot, \cdot \rangle$  denotes the generalized duality pairing. In the sequence, we will denote the single-valued duality mapping by  $j$ , and  $x_n \rightarrow x$  will denote strong convergence of the sequence  $\{x_n\}$  to  $x$ . In Banach space  $E$ , the following result is well known [1, 3] for all  $x, y \in E$ , for all  $j(x+y) \in J(x+y)$ , for all  $j(x) \in J(x)$ ,

$$\|x\|^2 + 2\langle y, j(x) \rangle \leq \|x+y\|^2 \leq \|x\|^2 + 2\langle y, j(x+y) \rangle. \quad (2.2)$$

Recall that the norm of  $E$  is said to be Gâteaux differentiable (and  $E$  is said to be smooth) if

$$\lim_{t \rightarrow 0} \frac{\|x+ty\| - \|x\|}{t} \quad (2.3)$$

exists for each  $x, y$  in its unit sphere  $U = \{x \in E : \|x\| = 1\}$ . It is said to be uniformly Gâteaux differentiable if, for each  $y \in U$ , this limit is attained uniformly for  $x \in U$ . Finally, the norm is said to be uniformly Fréchet differentiable (and  $E$  is said to be uniformly smooth) if the limit in (2.3) is attained uniformly for  $(x, y) \in U \times U$ . A Banach space  $E$  is said to be smooth if and only if  $J$  is single valued. It is also well known that if  $E$  is uniformly smooth,  $J$  is uniformly norm-to-norm continuous. These concepts may be found in [3].

If  $C$  and  $D$  are nonempty subsets of a Banach space  $E$  such that  $C$  is nonempty closed convex and  $D \subset C$ , then a mapping  $P : C \rightarrow D$  is called a retraction from  $C$  to  $D$  if  $P^2 = P$ . It is easily known that a mapping  $P : C \rightarrow D$  is retraction, then  $Px = x$ , for all  $x \in D$ . A mapping  $P : C \rightarrow D$  is called sunny if

$$P(Px + t(x - Px)) = Px \quad \forall x \in C, \quad (2.4)$$

whenever  $Px + t(x - Px) \in C$  and  $t > 0$ . A subset  $D$  of  $C$  is said to be a sunny nonexpansive retract of  $C$  if there exists a sunny nonexpansive retraction of  $C$  onto  $D$ . For more detail, see [1, 3–5].

The following lemma is well known [3].

LEMMA 2.1. *Let  $C$  be a nonempty convex subset of a smooth Banach space  $E$ ,  $D \in C$ ,  $J : E \rightarrow E^*$  the (normalized) duality mapping of  $E$ , and  $P : C \rightarrow D$  a retraction. Then the following are equivalent:*

- (i)  $\langle x - Px, j(y - Px) \rangle \leq 0$  for all  $x \in C$  and  $y \in D$ ;
- (ii)  $P$  is both sunny and nonexpansive.

Let  $C$  be a nonempty convex subset of a Banach space  $E$ , then for  $x \in C$ , we define the inward set [4, 5]:

$$I_C(x) = \{y \in E : y = x + \lambda(z - x), z \in C \text{ and } \lambda \geq 0\}. \tag{2.5}$$

A mapping  $T : C \rightarrow E$  is said to be satisfying the inward condition if  $Tx \in I_C(x)$  for all  $x \in C$ .  $T$  is also said to be satisfying the weakly inward condition if for each  $x \in C$ ,  $Tx \in \overline{I_C(x)}$  ( $\overline{I_C(x)}$  is the closure of  $I_C(x)$ ). Clearly  $C \subset \overline{I_C(x)}$  and it is not hard to show that  $I_C(x)$  is a convex set as  $C$  is. Using above these results and definitions, we can easily show the following lemma.

LEMMA 2.2 ([2], Lemma 1.2). *Let  $C$  be a nonempty closed subset of a smooth Banach space  $E$ , let  $T : C \rightarrow E$  be nonexpansive nonself-mapping satisfying the weakly inward condition, and let  $P$  be a sunny nonexpansive retraction of  $E$  onto  $C$ . Then  $F(T) = F(PT)$ .*

LEMMA 2.3 ([2], Lemma 2.1). *Let  $E$  be a Banach space and let  $C$  be a nonempty closed convex subset of  $E$ . Suppose that  $T : C \rightarrow E$  is a nonexpansive mapping such that for each fixed contractive mapping  $f : C \rightarrow C$ , and  $P$  is a sunny nonexpansive retraction of  $E$  onto  $C$ . For each  $t \in (0, 1)$ ,  $\{x_t\}$  is defined by (1.4). Suppose  $u \in C$  is a fixed point of  $T$ , then*

- (i)  $\langle x_t - f(x_t), j(x_t - u) \rangle \leq 0$ ;
- (ii)  $\{x_t\}$  is bounded.

Definition 2.4.  $\mu$  is called a Banach limit if  $\mu$  is a continuous linear functional on  $l^\infty$  satisfying

- (i)  $\|\mu(e)\| = 1 = \mu(1)$ ,  $e = (1, 1, 1, \dots)$ ;
- (ii)  $\mu_n(a_n) = \mu_n(a_{n+1})$ , for all  $a_n \in (a_0, a_1, \dots) \in l^\infty$ ;
- (iii)  $\liminf_{n \rightarrow \infty} a_n \leq \mu(a_n) \leq \limsup_{n \rightarrow \infty} a_n$ , for all  $a_n \in (a_0, a_1, \dots) \in l^\infty$ .

According to time and circumstances, we use  $\mu_n(a_n)$  instead of  $\mu(a_0, a_1, \dots)$ .

Further, we know the following result.

LEMMA 2.5 ([3], Lemma 4.5.4). *Let  $C$  be a nonempty closed convex subset of a Banach space  $E$  with a uniformly Gâteaux differentiable norm and let  $\{x_n\}$  be a bounded sequence in  $E$ . Let  $\mu$  be a Banach limit and  $u \in C$ . Then*

$$\mu_n \|x_n - u\|^2 = \min_{y \in C} \mu_n \|x_n - y\|^2 \tag{2.6}$$

#### 4 Strong convergence of approximation fixed points

if and only if

$$\mu_n \langle x - u, J(x_n - u) \rangle \leq 0 \quad (2.7)$$

for all  $x \in C$ .

### 3. Main results

**THEOREM 3.1.** *Let  $E$  be a uniformly smooth Banach, suppose that  $C$  is a nonempty closed convex subset of  $E$  and  $T : C \rightarrow E$  is a nonexpansive nonself-mapping satisfying the weakly inward condition and  $F(T) \neq \emptyset$ . Let  $f : C \rightarrow C$  be a fixed contractive mapping, and let  $\{x_t\}$  be defined by (1.4), where  $P$  is a sunny nonexpansive retraction of  $E$  onto  $C$ . Then as  $t \rightarrow 0$   $\{x_t\}$  converges strongly to some fixed point  $q$  of  $T$  that  $q$  is the unique solution in  $F(T)$  to the following variational inequality:*

$$\langle (I - f)q, j(q - u) \rangle \leq 0 \quad \forall u \in F(T). \quad (3.1)$$

*Proof.* For all  $u \in F(T)$  by Lemma 2.3(ii),  $\{x_t\}$  is bounded, therefore the sets  $\{Tx_t : t \in (0, 1)\}$  and  $\{f(x_t) : t \in (0, 1)\}$  are also bounded. From  $x_t = P(tf(x_t) + (1 - t)Tx_t)$ , we have

$$\begin{aligned} \|x_t - PTx_t\| &= \|P(tf(x_t) + (1 - t)Tx_t) - PTx_t\| \\ &\leq \|tf(x_t) + (1 - t)Tx_t - Tx_t\| \\ &= t\|Tx_t - f(x_t)\| \rightarrow 0 \quad \text{as } t \rightarrow 0. \end{aligned} \quad (3.2)$$

This implies that

$$\lim_{t \rightarrow 0} \|x_t - PTx_t\| = 0. \quad (3.3)$$

Assume  $t_n \rightarrow 0$ , set  $x_n := x_{t_n}$ , and define  $g : C \rightarrow \mathbb{R}$  by  $g(x) = \mu_n \|x_n - x\|^2$ ,  $x \in C$ , where  $\mu_n$  is a Banach limit on  $\ell^\infty$ . Let

$$K = \left\{ x \in C : g(x) = \min_{y \in C} \mu_n \|x_n - y\|^2 \right\}. \quad (3.4)$$

It is easily seen that  $K$  is a nonempty closed convex bounded subset of  $E$ , since (note  $\|x_n - Tx_n\| \rightarrow 0$ )

$$g(Tx) = \mu_n \|x_n - Tx\|^2 = \mu_n \|Tx_n - Tx\|^2 \leq \mu_n \|x_n - x\|^2 = g(x). \quad (3.5)$$

It follows that  $T(K) \subset K$ , that is,  $K$  is invariant under  $T$ . Since a uniformly smooth Banach space has the fixed point property for nonexpansive mappings,  $T$  has a fixed point, say  $q$ , in  $K$ . From Lemma 2.5 we get

$$\mu_n \langle x - q, j(x_n - q) \rangle \leq 0, \quad x \in C. \quad (3.6)$$

For all  $q \in F(T)$ , we have  $tf(x_t) + (1-t)q = P[tf(x_t) + (1-t)q]$ , then

$$\begin{aligned} & \|x_t - [tf(x_t) + (1-t)q]\| \\ &= \|P[tf(x_t) + (1-t)Tx_t] - P[tf(x_t) + (1-t)q]\| \\ &\leq \|(1-t)(Tx_t - q)\| \leq (1-t)\|x_t - q\|. \end{aligned} \tag{3.7}$$

Hence from (2.2) and the above inequality we get

$$\begin{aligned} & \|x_t - [tf(x_t) + (1-t)q]\|^2 \\ &= \|(1-t)(x_t - q) + t(x_t - f(x_t))\|^2 \\ &\geq (1-t)^2\|x_t - q\|^2 + 2t(1-t)\langle x_t - f(x_t), j(x_t - q) \rangle. \end{aligned} \tag{3.8}$$

Therefore

$$\langle x_t - f(x_t), j(x_t - q) \rangle \leq 0. \tag{3.9}$$

Then

$$\begin{aligned} 0 &\geq \langle x_t - f(x_t), j(x_t - q) \rangle \\ &= \|x_t - q\|^2 + \langle q - f(q), j(x_t - q) \rangle + \langle f(q) - f(x_t), j(x_t - q) \rangle \\ &\geq (1-\beta)\|x_t - q\|^2 + \langle q - f(q), j(x_t - q) \rangle. \end{aligned} \tag{3.10}$$

We get

$$\|x_t - q\|^2 \leq \frac{1}{1-\beta} \langle f(q) - q, j(x_t - q) \rangle. \tag{3.11}$$

Now applying Banach limit to the above inequality, we get

$$\mu_n \|x_t - q\|^2 \leq \mu_n \left( \frac{1}{1-\beta} \langle f(q) - q, j(x_t - q) \rangle \right). \tag{3.12}$$

Let  $x = f(q)$  in (3.6), and noting (3.12), we have

$$\mu_n \|x_t - q\|^2 \leq 0, \tag{3.13}$$

that is,

$$\mu_n \|x_n - q\|^2 = 0 \tag{3.14}$$

and then exists a subsequence which is still denoted by  $\{x_n\}$  such that

$$x_n \longrightarrow q, \quad n \longrightarrow \infty. \tag{3.15}$$

We have proved that for any sequence  $\{x_{t_n}\}$  in  $\{x_t : t \in (0,1)\}$ , there exists a subsequence which is still denoted by  $\{x_{t_n}\}$  that converges to some point  $q$  of  $T$ . To prove that

## 6 Strong convergence of approximation fixed points

the entire net  $\{x_t\}$  converges to  $q$ , suppose that there exists another sequence  $\{x_{s_k}\} \subset \{x_t\}$  such that  $x_{s_k} \rightarrow p$ , as  $s_k \rightarrow 0$ , then we also have  $p \in F(T)$  (using  $\lim_{t \rightarrow 0} \|x_t - PTx_t\| = 0$ ). Next we show  $p = q$  and  $q$  is the unique solution in  $F(T)$  to the following variational inequality:

$$\langle (I - f)q, j(q - u) \rangle \quad \forall u \in F(T). \quad (3.16)$$

Since the sets  $\{x_t - u\}$  and  $\{x_t - f(x_t)\}$  are bounded and the uniform smoothness of  $E$  implies that the duality map  $J$  is norm-to-norm uniformly continuous on bounded sets of  $E$ , for any  $u \in F(T)$ , by  $x_{s_k} \rightarrow p$  ( $s_k \rightarrow 0$ ), we have

$$\begin{aligned} & \| (I - f)x_{s_k} - (I - f)p \| \rightarrow 0, \quad s_k \rightarrow 0, \\ & | \langle x_{s_k} - f(x_{s_k}), j(x_{s_k} - u) \rangle - \langle (I - f)p, j(p - u) \rangle | \\ &= | \langle x_{s_k} - f(x_{s_k}) - (I - f)p, j(x_{s_k} - u) \rangle - \langle (I - f)p, j(x_{s_k} - u) - j(p - u) \rangle | \\ &\leq \| (I - f)x_{s_k} - (I - f)p \| \| x_{s_k} - u \| \\ &\quad + | \langle (I - f)p, j(x_{s_k} - u) - j(p - u) \rangle | \rightarrow 0 \quad \text{as } s_k \rightarrow 0. \end{aligned} \quad (3.17)$$

Therefore, noting Lemma 2.3(i), for any  $u \in F(T)$ , we get

$$\langle (I - f)p, j(p - u) \rangle = \lim_{s_k \rightarrow 0} \langle x_{s_k} - f(x_{s_k}), j(x_{s_k} - u) \rangle \leq 0. \quad (3.18)$$

Similarly, we also can show

$$\langle (I - f)q, j(q - u) \rangle = \langle x_{t_n} - f(x_{t_n}), j(x_{t_n} - u) \rangle \leq 0. \quad (3.19)$$

Interchange  $q$  and  $u$  to obtain

$$\langle (I - f)p, j(p - q) \rangle \leq 0. \quad (3.20)$$

Interchange  $p$  and  $u$  to obtain

$$\langle (I - f)q, j(q - p) \rangle \leq 0. \quad (3.21)$$

This implies that

$$\langle (p - q) - (f(p) - f(q)), j(p - q) \rangle \leq 0, \quad (3.22)$$

that is,

$$\| p - q \|^2 \leq \beta \| p - q \|^2. \quad (3.23)$$

This is a contradiction, so we must have  $q = p$ .

The proof is complete.  $\square$

From Theorem 3.1 we can get the following corollary directly.

**COROLLARY 3.2.** *Let  $E$  be a uniformly smooth space, suppose  $C$  is a nonempty closed convex subset of  $E$ ,  $T : C \rightarrow E$  is a nonexpansive mapping satisfying the weakly inward condition, and  $F(T) \neq \emptyset$ . Let  $f : C \rightarrow C$  be a fixed contractive mapping from  $C$  to  $C$ .  $\{x_t\}$  is defined by*

$$x_t = tf(x_t) + (1-t)PTx_t, \quad (3.24)$$

where  $P$  is a sunny nonexpansive retraction of  $E$  onto  $C$ , then  $x_t$  converges strongly to some fixed point  $q$  of  $T$  as  $t \rightarrow 0$  and  $q$  is the unique solution in  $F(T)$  to the following variational inequality:

$$\langle (I-f)q, j(q-u) \rangle \quad \forall u \in F(T). \quad (3.25)$$

**LEMMA 3.3** ([6], Lemma 2.1). *Let  $\{\alpha_n\}$  be a sequence of nonnegative real numbers satisfying the property*

$$\alpha_{n+1} \leq (1-\gamma_n)\alpha_n + \delta_n \quad \forall n \geq 0, \quad (3.26)$$

where  $\{\gamma_n\} \in (0, 1)$  and  $\delta_n$  is a sequence in  $\mathbb{R}$  such that:

- (i)  $\lim_{n \rightarrow \infty} \gamma_n = 0$  and  $\sum_{n=0}^{\infty} \gamma_n = \infty$ ;
  - (ii) either  $\sum_{n=0}^{\infty} \delta_n < +\infty$  or  $\limsup_{n \rightarrow \infty} (\delta_n/\gamma_n) \leq 0$ ,
- then  $\lim_{n \rightarrow \infty} \alpha_n = 0$ .

**THEOREM 3.4.** *Let  $E$  be a uniformly smooth Banach space, suppose that  $C$  is a nonempty closed convex subset of  $E$ ,  $T : C \rightarrow E$  is a nonexpansive nonself-mapping satisfying the weakly inward condition, and  $F(T) \neq \emptyset$ . Let  $f : C \rightarrow C$  be a fixed contractive mapping, and  $\{x_n\}$  is defined by (1.5), where  $P$  is a sunny nonexpansive retraction of  $E$  onto  $C$ , and  $\alpha_n \in (0, 1)$  satisfies the following conditions:*

- (i)  $\alpha_n \rightarrow 0$ , as  $n \rightarrow \infty$ ;
- (ii)  $\sum_{n=0}^{\infty} \alpha_n = \infty$ ;
- (iii) either  $\sum_{n=0}^{\infty} |\alpha_{n+1} - \alpha_n| < \infty$  or  $\lim_{n \rightarrow \infty} (\alpha_{n+1}/\alpha_n) = 1$ .

Then  $x_n$  converges strongly to a fixed point  $q$  of  $T$  such that  $q$  is the unique solution in  $F(T)$  to the following variational inequality:

$$\langle (I-f)q, j(q-u) \rangle \leq 0 \quad \forall u \in F(T). \quad (3.27)$$

*Proof.* First we show  $\{x_n\}$  is bounded. Take  $u \in F(T)$ , it follows that

$$\begin{aligned} \|x_{n+1} - u\| &= \|P((1-\alpha_n)Tx_n + \alpha_n f(x_n)) - Pu\| \\ &\leq \|(1-\alpha_n)Tx_n + \alpha_n f(x_n) - u\| \\ &\leq (1-\alpha_n)\|Tx_n - u\| + \alpha_n(\|f(x_n) - f(u)\| + \|f(u) - u\|) \\ &\leq (1-\alpha_n)\|x_n - u\| + \alpha_n(\beta\|x_n - u\| + \|f(u) - u\|) \\ &= (1-(1-\beta)\alpha_n)\|x_n - u\| + \alpha_n\|f(u) - u\| \\ &\leq \max\left\{\|x_n - u\|, \frac{1}{1-\beta}\|f(u) - u\|\right\}. \end{aligned} \quad (3.28)$$

## 8 Strong convergence of approximation fixed points

By induction,

$$\|x_n - u\| \leq \max \left\{ \|x_0 - u\|, \frac{1}{1-\beta} \|f(u) - u\| \right\}, \quad n \geq 0, \quad (3.29)$$

and  $\{x_n\}$  is bounded, so are  $\{Tx_n\}$  and  $\{f(x_n)\}$ . We claim that

$$x_{n+1} - x_n \rightarrow 0 \quad \text{as } n \rightarrow \infty. \quad (3.30)$$

Indeed we have (for some appropriate constant  $M > 0$ )

$$\begin{aligned} \|x_{n+1} - x_n\| &= \|P(\alpha_n f(x_n) + (1 - \alpha_n)Tx_n) - P(\alpha_{n-1}f(x_{n-1}) + (1 - \alpha_{n-1})Tx_{n-1})\| \\ &\leq \|\alpha_n f(x_n) + (1 - \alpha_n)Tx_n - \alpha_{n-1}f(x_{n-1}) - (1 - \alpha_{n-1})Tx_{n-1}\| \\ &\leq \|(1 - \alpha_n)(Tx_n - Tx_{n-1}) + (\alpha_n - \alpha_{n-1})(f(x_{n-1}) - Tx_{n-1})\| \\ &\quad + \alpha_n \|f(x_n) - f(x_{n-1})\| \\ &\leq (1 - \alpha_n)\|x_n - x_{n-1}\|[3pt] + M|\alpha_n - \alpha_{n-1}| + \beta\alpha_n\|x_n - x_{n-1}\| \\ &= (1 - (1 - \beta)\alpha_n)\|x_n - x_{n-1}\|[3pt] + M|\alpha_n - \alpha_{n-1}|. \end{aligned} \quad (3.31)$$

By Lemma 3.3 we have  $\|x_{n+1} - x_n\| \rightarrow 0$ , as  $n \rightarrow \infty$ . We now show that

$$\|x_n - PTx_n\| \rightarrow 0. \quad (3.32)$$

In fact,

$$\begin{aligned} \|x_{n+1} - PTx_n\| &= \|P(\alpha_n f(x_n) + (1 - \alpha_n)Tx_n) - PTx_n\| \\ &\leq \alpha_n \|f(x_n) - Tx_n\|. \end{aligned} \quad (3.33)$$

This follows from (3.30) that

$$\begin{aligned} \|x_n - PTx_n\| &\leq \|x_n - x_{n+1}\| + \|x_{n+1} - PTx_n\| \\ &\leq \|x_n - x_{n+1}\| + \alpha_n \|f(x_n) - Tx_n\| \rightarrow 0 \quad \text{as } n \rightarrow \infty. \end{aligned} \quad (3.34)$$

Let  $q = \lim_{t \rightarrow 0} x_t$ , where  $\{x_t\}$  is defined in Corollary 3.2, we get that  $q$  is the unique solution in  $F(T)$  to the following variational inequality:

$$\langle (I - f)q, j(q - u) \rangle \leq 0 \quad \forall u \in F(T). \quad (3.35)$$

We next show that

$$\limsup_{n \rightarrow \infty} \langle f(q) - q, j(x_n - q) \rangle \leq 0. \quad (3.36)$$

Form Corollary 3.2, let  $x_t = tf(x_t) + (1-t)PTx_t$ , indeed we can write

$$x_t - x_n = t(f(x_t) - x_n) + (1-t)(PTx_t - x_n). \quad (3.37)$$

Noting (3.32), putting

$$a_n(t) = \|x_n - PTx_n\|(\|x_n - PTx_n\| + 2\|x_n - x_t\|) \rightarrow 0 \quad \text{as } n \rightarrow \infty, \quad (3.38)$$

and using (2.2), we obtain

$$\begin{aligned} & \|x_t - x_n\|^2 \\ & \leq (1-t)^2 \|PTx_t - x_n\|^2 + 2t \langle f(x_t) - x_n, j(x_t - x_n) \rangle \\ & \leq (1-t)^2 \|PTx_t - PTx_n + PTx_n - x_n\|^2 + 2t \langle f(x_t) - x_t, j(x_t - x_n) \rangle \\ & \quad + 2t \|x_t - x_n\|^2 \leq (1-t)^2 \|x_t - x_n\|^2 + (1-t)^2 \|x_n - PTx_n\|^2 \\ & \quad + 2(1-t)^2 \|PTx_n - x_n\| \|x_t - x_n\| + 2t \langle f(x_t) - x_t, j(x_t - x_n) \rangle + 2t \|x_t - x_n\|^2 \\ & \leq (1+t^2) \|x_t - x_n\|^2 + a_n(t) + 2t \langle f(x_t) - x_t, j(x_t - x_n) \rangle. \end{aligned} \quad (3.39)$$

The last inequality implies

$$\langle f(x_t) - x_t, j(x_n - x_t) \rangle \leq \frac{t}{2} \|x_t - x_n\|^2 + \frac{1}{2t} a_n(t). \quad (3.40)$$

From  $a_n(t) \rightarrow 0$  as  $n \rightarrow \infty$  we get

$$\limsup_{n \rightarrow \infty} \langle f(x_t) - x_t, j(x_n - x_t) \rangle \leq M \cdot \frac{t}{2}, \quad (3.41)$$

where  $M > 0$  is a constant such that  $M \geq \|x_t - x_n\|^2$  for all  $n \geq 0$  and  $t \in (0, 1)$ . By letting  $t \rightarrow 0$  in (3.41) we have

$$\lim_{t \rightarrow 0} \limsup_{n \rightarrow \infty} \langle f(x_t) - x_t, j(x_n - x_t) \rangle \leq 0. \quad (3.42)$$

On the one hand, for all  $\varepsilon > 0$ ,  $\exists \delta_1$  such that  $t \in (0, \delta_1)$ ,

$$\limsup_{n \rightarrow \infty} \langle f(x_t) - x_t, j(x_n - x_t) \rangle \leq \frac{\varepsilon}{2}. \quad (**)$$

## 10 Strong convergence of approximation fixed points

On the other hand,  $\{x_t\}$  strongly converges to  $q$ , as  $t \rightarrow 0$ , the set  $\{x_t - x_n\}$  is bounded, and the duality map  $J$  is norm-to-norm uniformly continuous on bounded sets of uniformly smooth space  $E$ ; from  $x_t \rightarrow q$  ( $t \rightarrow 0$ ), we get

$$\begin{aligned}
 & \|f(q) - q - (f(x_t) - x_t)\| \rightarrow 0, \quad t \rightarrow 0, \\
 & \| \langle f(q) - q, j(x_n - q) \rangle - \langle f(x_t) - x_t, j(x_n - x_t) \rangle \| \\
 &= \| \langle f(q) - q, j(x_n - q) - j(x_n - x_t) \rangle + \langle f(q) - q - (f(x_t) - x_t), j(x_n - x_t) \rangle \| \\
 &\leq \|f(q) - q\| \|j(x_n - q) - j(x_n - x_t)\| \\
 &\quad + \|f(q) - q - (f(x_t) - x_t)\| \|x_n - x_t\| \rightarrow 0, \quad t \rightarrow 0.
 \end{aligned} \tag{3.43}$$

Hence for the above  $\varepsilon > 0$ ,  $\exists \delta_2$ , such that for all  $t \in (0, \delta_2)$ , for all  $n$ , we have

$$\| \langle f(q) - q, j(x_n - q) \rangle - \langle f(x_t) - x_t, j(x_n - x_t) \rangle \| \leq \frac{\varepsilon}{2}. \tag{3.44}$$

Therefore, we have

$$\langle f(q) - q, j(x_n - q) \rangle \leq \langle f(x_t) - x_t, j(x_n - x_t) \rangle + \frac{\varepsilon}{2}. \tag{3.45}$$

Noting (\*\*) and taking  $\delta = \min\{\delta_1, \delta_2\}$ , for all  $t \in (0, \delta)$ , we have

$$\begin{aligned}
 & \limsup_{n \rightarrow \infty} \langle f(q) - q, j(x_n - q) \rangle \\
 &\leq \limsup_{n \rightarrow \infty} \left( \langle f(x_t) - x_t, j(x_n - x_t) \rangle + \frac{\varepsilon}{2} \right) \leq \frac{\varepsilon}{2} + \frac{\varepsilon}{2} = \varepsilon.
 \end{aligned} \tag{3.46}$$

Since  $\varepsilon$  is arbitrary, we get

$$\limsup_{n \rightarrow \infty} \langle f(q) - q, j(x_n - q) \rangle \leq 0. \tag{3.47}$$

Finally we show  $x_n \rightarrow q$ . Indeed

$$x_{n+1} - (\alpha_n f(x_n) + (1 - \alpha_n)q) = (x_{n+1} - q) - \alpha_n (f(x_n) - q). \tag{3.48}$$

By (2.2) we have

$$\begin{aligned}
\|x_{n+1} - q\|^2 &= \|x_{n+1} - (\alpha_n f(x_n) + (1 - \alpha_n)q) + \alpha_n(f(x_n) - q)\|^2 \\
&\leq \|x_{n+1} - P(\alpha_n f(x_n) + (1 - \alpha_n)q)\|^2 + 2\alpha_n \langle f(x_n) - q, j(x_{n+1} - q) \rangle \\
&\leq \|P[\alpha_n f(x_n) + (1 - \alpha_n)Tx_n] - P(\alpha_n f(x_n) + (1 - \alpha_n)q)\|^2 \\
&\quad + 2\alpha_n \langle f(x_n) - q, j(x_{n+1} - q) \rangle \\
&\leq (1 - \alpha_n)^2 \|Tx_n - q\|^2 + 2\alpha_n \langle f(x_n) - f(q), j(x_{n+1} - q) \rangle \\
&\quad + 2\alpha_n \langle f(q) - q, j(x_{n+1} - q) \rangle \\
&\leq (1 - \alpha_n)^2 \|x_n - q\|^2 + 2\alpha_n \|f(q) - f(x_n)\| \|x_{n+1} - q\| \\
&\quad + 2\alpha_n \langle f(q) - q, j(x_{n+1} - q) \rangle \\
&\leq (1 - \alpha_n)^2 \|x_n - q\|^2 + \alpha_n (\|f(q) - f(x_n)\|^2 + \|x_{n+1} - q\|^2) \\
&\quad + 2\alpha_n \langle f(q) - q, j(x_{n+1} - q) \rangle.
\end{aligned} \tag{3.49}$$

Therefore, we have

$$\begin{aligned}
(1 - \alpha_n) \|x_{n+1} - q\|^2 \\
\leq (1 - \alpha_n)^2 \|x_n - q\|^2 + \alpha_n \beta^2 \|x_n - q\|^2 + 2\alpha_n \langle f(q) - q, j(x_{n+1} - q) \rangle.
\end{aligned} \tag{3.50}$$

That is,

$$\begin{aligned}
\|x_{n+1} - q\|^2 &\leq \left(1 - \frac{1 - \beta^2}{1 - \alpha_n} \alpha_n\right) \|x_n - q\|^2 + \frac{\alpha_n^2}{1 - \alpha_n} \|x_n - q\|^2 \\
&\quad + \frac{2\alpha_n}{1 - \alpha_n} \langle f(q) - q, j(x_{n+1} - q) \rangle \\
&\leq (1 - \gamma_n) \|x_n - q\|^2 + \lambda \gamma_n \alpha_n + \frac{2}{1 - \beta^2} \gamma_n \langle f(q) - q, j(x_{n+1} - q) \rangle,
\end{aligned} \tag{3.51}$$

where  $\gamma_n = ((1 - \beta^2)/(1 - \alpha_n))\alpha_n$  and  $\lambda$  is a constant such that  $\lambda > (1/(1 - \beta^2))\|x_n - q\|^2$ .

Hence,

$$\|x_{n+1} - q\|^2 \leq (1 - \gamma_n) \|x_n - q\|^2 + \gamma_n \left( \lambda \alpha_n + \frac{2}{1 - \beta^2} \langle f(q) - q, j(x_{n+1} - q) \rangle \right). \tag{3.52}$$

It is easily seen that  $\gamma_n \rightarrow 0$ ,  $\sum_{n=1}^{\infty} \gamma_n = \infty$ , and (noting (3.36))

$$\limsup_{n \rightarrow \infty} \left( \lambda \alpha_n + \frac{2}{1 - \beta^2} \langle f(q) - q, j(x_{n+1} - q) \rangle \right) \leq 0. \tag{3.53}$$

Applying Lemma 3.3 onto (3.52), we have  $x_n \rightarrow q$ .

The proof is complete.  $\square$
