Abstract

For any set of positive and relatively prime integers A, the set of positive integers that are not representable as a nonnegative integral linear combination of elements of A is always a non-empty finite set. Thus we may define $\mathrm{g}(A)$, $\mathrm{n}(A)$, $\mathrm{s}(A)$ to denote the largest integer in, the number of integers in, and the sum of integers in this finite set, respectively. We determine $\mathrm{g}(A)$, $\mathrm{n}(A)$, $\mathrm{s}(A)$ when $A = \{a, b, c\}$ with $a \mid \mathrm{lcm}(b, c)$. A particular case of this is when $A = \{k\ell, \ell m, mk\}$, with k, ℓ, m pairwise coprime. We also solve a related problem when $a \mid \mathrm{lcm}(b, c)$, thereby providing another proof of the formula for $\mathrm{g}(A)$.

1 Introduction

The following problem was the third of the six problems in the Twenty-Fourth International Mathematical Olympiad, held in Paris on July 6–7, 1983:

> Let a, b, c be positive integers satisfying $(a, b) = (b, c) = (c, a) = 1$. Show that $2abc - ab - bc - ca$ is the largest integer not representable as
>
> $$xbc + yca + zab$$
>
> with nonnegative integers x, y, z.

This is a special case of the well-known linear Diophantine problem, posed by Sylvester [7], but known as the *Frobenius problem*, after G. Frobenius who was largely instrumental in popularizing the problem. Consider a finite set $A = \{a_1, \ldots, a_k\}$ of positive integers with $\gcd A := \gcd(a_1, \ldots, a_k) = 1$. Let $\Gamma(A) := \{a_1x_1 + \cdots + a_kx_k : x_i \in \mathbb{Z}_{\geq 0}\}$. Then $\Gamma^c(A) := \mathbb{Z}_{\geq 0} \setminus \Gamma(A)$ can be shown to be a *finite* set, and this allows us to define the *Frobenius number* $\mathrm{g}(A)$ and the *Sylvester number* $\mathrm{n}(A)$:

$$\mathrm{g}(A) := \max \Gamma^c(A), \quad \mathrm{n}(A) := \big|\Gamma^c(A)\big|.$$

Here, and elsewhere, $|X|$ denotes the cardinality of the finite set X. The Frobenius problem is to determine $\mathrm{g}(A)$ and $\mathrm{n}(A)$ in the general case.

For $A = \{a, b\}$, $\gcd(a, b) = 1$, Sylvester [7] showed

$$\mathrm{g}(a, b) = ab - a - b, \quad \mathrm{n}(a, b) = \frac{1}{2}(a - 1)(b - 1).$$

Exact values for $\mathrm{g}(A)$ have been known only for few cases when $|A| > 2$ – in some cases when the elements of A satisfy a specific condition. For instance, $\mathrm{g}(k\ell, \ell m, mk) = 2k\ell m - k\ell - \ell m - mk$ whenever $\gcd(k, \ell) = \gcd(\ell, m) = \gcd(m, k) = 1$. On the other hand, bounds and algorithms to compute $\mathrm{g}(A)$, especially in the case $|A| = 3$, have been a major source of research. Corresponding results for $\mathrm{n}(A)$ have been much rarer, even in special cases; refer to [4].

Brown and Shiue [1] introduced the related problem of determining the function

$$\mathrm{s}(A) := \sum_{n \in \Gamma^c(A)} n,$$

and found

$$\mathrm{s}(a, b) = \frac{1}{12}(a - 1)(b - 1)(2ab - a - b - 1)$$

when $\gcd(a, b) = 1$; also see [10].

Tripathi [8] introduced the following variation on the Frobenius problem. The set $\Gamma(A)$ is closed under addition, and so $n + \Gamma(A) \subseteq \Gamma(A)$ whenever $n \in \Gamma(A)$. It is conceivable that $n \in \Gamma^c(A)$ satisfy a slightly modified condition, replacing $\Gamma(A)$ by $\Gamma(A) \setminus \{0\}$. In fact, $\mathrm{g}(A)$ is clearly the largest number satisfying such a condition. Thus we study the set given by

$$\mathcal{S}^\star(A) := \big\{n \in \Gamma^c(A) : n + \Gamma^\star(A) \subset \Gamma^\star(A)\big\},$$

where $\Gamma^\star(A) = \Gamma(A) \setminus \{0\}$.

In this note, we consider the set $A = \{a, b, c\}$ with $\gcd(a, b) = 1$, where a divides $\mathrm{lcm}(b, c)$. Observe that the IMO problem introduced at the beginning of this article, involving triples $a = k\ell$, $b = \ell m$, $c = mk$ with k, ℓ, m pairwise coprime, satisfies the condition a divides $\mathrm{lcm}(b, c)$. We determine $\mathrm{g}(A)$, $\mathrm{n}(A)$, $\mathrm{s}(A)$, and the set $\mathcal{S}^\star(A)$, giving more than one proof for each of the results for $\mathrm{g}(A)$ and $\mathrm{n}(A)$. We list all results that we will base our study on

in Section 2, and prove our main results, listed as Theorem 1 and Corollary 2, in Section 3. The results of Corollary 2 follow directly from those of Theorem 1, and the results for $\mathrm{g}(A)$, $\mathrm{n}(A)$ and $\mathcal{S}^\star(A)$ are also special cases of [9, Theorem 1, 2]. The proofs of the results in Corollary 2 are omitted.

Theorem 1. *Let $A = \{a, b, c\}$, where $\gcd(a, b, c) = 1$ and $a \mid \mathrm{lcm}(b, c)$. Then*

(a)
$$\mathrm{g}(a, b, c) = \mathrm{lcm}(a, b) + \mathrm{lcm}(a, c) - (a + b + c).$$

(b)
$$\mathrm{n}(a, b, c) = \frac{1}{2}\Big(\mathrm{lcm}(a, b) + \mathrm{lcm}(a, c) - (a + b + c) + 1\Big).$$

(c)
$$\begin{aligned}\mathrm{s}(a, b, c) \;=\; & \frac{1}{12}\Big(a^2 + b^2 + c^2 + 3abc + 3(ab + bc + ca) - 3(a + b + c)\big(\mathrm{lcm}(a, b) + \mathrm{lcm}(a, c)\big)\\ & +2\big(\big(\mathrm{lcm}(a, b)\big)^2 + \big(\mathrm{lcm}(a, c)\big)^2\big) - 1\Big).\end{aligned}$$

(d)
$$\mathcal{S}^\star(\{a, b, c\}) = \Big\{ \mathrm{lcm}(a, b) + \mathrm{lcm}(a, c) - (a + b + c)\Big\}.$$

Corollary 2. *Let k, ℓ, m be pairwise coprime, positive integers. If $\sigma_1 = k + \ell + m$, $\sigma_2 = k\ell + \ell m + mk$, and $\sigma_3 = k\ell m$, then*

$$\mathrm{g}(k\ell, \ell m, mk) = 2\sigma_3 - \sigma_2, \quad \mathrm{n}(k\ell, \ell m, mk) = \frac{1}{2}\big(2\sigma_3 - \sigma_2 + 1\big),$$
$$\mathrm{s}(k\ell, \ell m, mk) = \frac{1}{12}\big(7\sigma_3^2 - 6\sigma_2\,\sigma_3 + \sigma_2^2 + \sigma_1\,\sigma_3 - 1\big), \quad \mathcal{S}^\star\big(\{k\ell, \ell m, mk\}\big) = \big\{2\sigma_3 - \sigma_2\big\}.$$

2 Preliminary results

Suppose A is any set of positive integers with $\gcd A = 1$, and let $a \in A$. For each residue class $\mathbf{C}$ modulo a, let $\mathbf{m_C}$ denote the least integer in $\Gamma(A) \cap \mathbf{C}$. It is well known that the functions g, n and s are easily determined from the values of $\mathbf{m_C}$. The following result, part (i) of which is due to Brauer and Shockley [2], part (ii) to Selmer [6], and part (iii) to Tripathi [10], is often a key step in this determination.

Proposition 3. **[2, 6, 10]**
Let A be any set of positive integers with $\gcd(A) = 1$. For any $a \in A$,

$$\mathrm{g}(A) = \Big(\max_{\mathbf{C}}\, \mathbf{m_C}\Big) - a, \quad \mathrm{n}(A) = \frac{1}{a}\sum_{\mathbf{C}} \mathbf{m_C} - \frac{1}{2}(a - 1),$$
$$\mathrm{s}(A) = \frac{1}{2a}\sum_{\mathbf{C}} \mathbf{m_C}^2 - \frac{1}{2}\sum_{\mathbf{C}} \mathbf{m_C} + \frac{1}{12}(a^2 - 1),$$

where the maximum and the sums are taken over all nonzero classes $\mathbf{C}$ *modulo* a.

Generating functions naturally enter as a tool in the study of the Frobenius problem. The results in Proposition 4 are the combinatorial analogues of the corresponding results in Proposition 3. The generating function f_A for the set A can be used to evaluate the functions g and n (this is almost folklore, but the evaluation of n in this manner actually appears in [7]). The use of the function f_A to evaluate $\mathrm{s}(A)$ is due to Brown and Shiue [1]; in fact, they used this method to determine $\mathrm{s}(a, b)$.

Proposition 4. [1, 7]
Let A *be any set of positive integers with* $\gcd(A) = 1$. *Set*

$$f_A(t) = \sum_{a \in A} t^a.$$

Then

$$f_{\Gamma^c(A)}(t) = \frac{1}{1-t} - f_{\Gamma(A)}(t),$$

and

$$\mathrm{g}(A) = deg\, f_{\Gamma^c(A)}(t), \quad \mathrm{n}(A) = \lim_{t \to 1} f_{\Gamma^c(A)}(t), \quad \mathrm{s}(A) = \lim_{t \to 1} f'_{\Gamma^c(A)}(t).$$

The following reduction formulae for $\mathrm{g}(A)$, due to Johnson [3] for the three variable case and to Brauer and Shockley [2] for the general case, and for $\mathrm{n}(A)$ due to Rødseth [5], are useful in cases when all but one member of A share a common divisor greater than 1.

Proposition 5. [2, 5]
Let A *be any set of positive integers with* $\gcd(A) = 1$. *If* $a \in A$ *is such that* $\gcd(A \setminus \{a\}) = d$, *and* $A' = \frac{1}{d}\big(A \setminus \{a\}\big)$, *then*

$$\mathrm{g}\big(A\big) = d \cdot \mathrm{g}\big(A' \cup \{a\}\big) + a(d-1), \quad \mathrm{n}\big(A\big) = d \cdot \mathrm{n}\big(A' \cup \{a\}\big) + \tfrac{1}{2}(a-1)(d-1).$$

The set $\mathcal{S}^\star(A)$ consists of integers n in $\Gamma^c(A)$ such that translating the set of positive integers in $\Gamma(A)$ by n results in a subset of $\Gamma(A)$. Since $\mathrm{g}(A) \in \mathcal{S}^\star(A)$, determining $\mathcal{S}^\star(A)$ ensures that $\mathrm{g}(A)$ is also determined. The following result is due to Tripathi [8].

Proposition 6. [8]
Let A *be any set of positive integers with* $\gcd(A) = 1$. *Let* $a \in A$, *and let* $\mathbf{m}_x$ *denote the least integer in* $\Gamma(A)$ *congruent to* x *modulo* a, $1 \le x \le a-1$. *Then*

$$\mathcal{S}^\star(A) = \big\{\mathbf{m}_x - a : \mathbf{m}_x + \mathbf{m}_y \ge \mathbf{m}_{x+y} + a \text{ for } 1 \le y \le a-1\big\}.$$

3 Main results

Throughout this section, we consider the set $A = \{a, b, c\}$ with $\gcd(a, b, c) = 1$ and $a \mid \operatorname{lcm}(b, c)$. We prove Theorem 1 by using the results in Section 2. More specifically, we use Proposition 3 and Proposition 5 to determine both $\mathrm{g}(A)$ and $\mathrm{n}(A)$. We also use Proposition 3 to determine $\mathrm{s}(A)$. We use Proposition 4 to determine $\mathrm{g}(A)$ and $\mathrm{n}(A)$ via the proofs using Proposition 3. Finally, we use Proposition 6 to determine $\mathcal{S}^\star(A)$, which incidentally also provides another proof for the formula for $\mathrm{g}(A)$. The result of Corollary 2 is a direct consequence of Theorem 1; the details are omitted.

3.1 Determining $\mathrm{g}(A)$ and $\mathrm{n}(A)$ from Proposition 5

We first use the reduction formula given in Proposition 5 to determine both $\mathrm{g}(A)$ and $\mathrm{n}(A)$. The following lemma is crucial to many results in this section.

Lemma 7. *Suppose a, b, c are positive integers, with $\gcd(a, b, c) = 1$. If $a \mid \operatorname{lcm}(b, c)$, then $a = \gcd(a, b) \cdot \gcd(a, c)$.*

Proof. Let p be a prime divisor of a, and let p^α, p^β, p^γ be the highest power of p dividing a, b, c, respectively. Then $0 = \min\{\beta, \gamma\} < \alpha \le \max\{\beta, \gamma\}$. Thus $a = rs$, where $r = \gcd(a, b)$, $s = \gcd(a, c)$ and $\gcd(r, s) = 1$. □

Proof of Theorem 1, (a) and (b).
From Lemma 7 we have $a = rs$, where $r = \gcd(a, b)$, $s = \gcd(a, c)$ and $\gcd(r, s) = 1$. Note that $bs = ab/r = \operatorname{lcm}(a, b)$ and $cr = ac/s = \operatorname{lcm}(a, c)$.

If $1 \in A$, then $\Gamma(A) = \mathbb{Z}_{\ge 0}$, and so we define $\mathrm{g}(A) = -1$ in this case. We apply Proposition 5.

(a)

$$\begin{aligned}
\mathrm{g}(a, b, c) &= r \cdot \mathrm{g}\left(\tfrac{a}{r}, \tfrac{b}{r}, c\right) + c(r-1) \\
&= r\left(s \cdot \mathrm{g}\left(1, \tfrac{b}{r}, \tfrac{c}{s}\right) + \tfrac{b}{r}(s-1)\right) + c(r-1) \\
&= a \cdot \mathrm{g}\left(1, \tfrac{b}{r}, \tfrac{c}{s}\right) + b(s-1) + c(r-1) \\
&= bs + cr - a - b - c \\
&= \operatorname{lcm}(a, b) + \operatorname{lcm}(a, c) - (a + b + c).
\end{aligned}$$

(b)

$$\begin{aligned}
\mathrm{n}(a,b,c) &= r\cdot \mathrm{n}\left(\tfrac{a}{r},\tfrac{b}{r},c\right)+\tfrac{1}{2}(c-1)(r-1)\\
&= r\Big(s\cdot \mathrm{n}\left(1,\tfrac{b}{r},\tfrac{c}{s}\right)+\tfrac{1}{2}\left(\tfrac{b}{r}-1\right)(s-1)\Big)+\tfrac{1}{2}(c-1)(r-1)\\
&= a\cdot \mathrm{n}\left(1,\tfrac{b}{r},\tfrac{c}{s}\right)+\tfrac{1}{2}(b-r)(s-1)+\tfrac{1}{2}(c-1)(r-1)\\
&= \tfrac{1}{2}(b-r)(s-1)+\tfrac{1}{2}(c-1)(r-1)\\
&= \tfrac{1}{2}\big(bs+cr-rs-b-c+1\big)\\
&= \tfrac{1}{2}\Big(\operatorname{lcm}(a,b)+\operatorname{lcm}(a,c)-(a+b+c)+1\Big).
\end{aligned}$$

□

3.2 Determining g(A), n(A) and s(A) from Proposition 3

We next use Proposition 3 to determine g(A), n(A), and s(A). This requires the determination of $\mathbf{m_C}$ for each nonzero residue class $\mathbf{C}$ modulo a. We note that the maximum and the sum in Proposition 3 may also be taken to include $\mathbf{m}_0 = 0$.

Theorem 8. *Let $A = \{a,b,c\}$, where $\gcd(a,b,c) = 1$ and $a \mid \operatorname{lcm}(b,c)$. Let $\mathbf{m}_i$ denote the least integer in $\Gamma(\{a,b,c\})$ which is congruent to i modulo a. Then*

$$\big\{\mathbf{m}_i : 0 \le i \le a-1\big\} = \big\{bx+cy : 0 \le x \le s-1, 0 \le y \le r-1\big\},$$

where $r = \gcd(a,b)$ and $s = \gcd(a,c)$.

Proof. Suppose $bx_1+cy_1 \equiv bx_2+cy_2 \pmod a$ with $0 \le x_1, x_2 \le s-1$ and $0 \le y_1, y_2 \le r-1$. Then $bx_0 \equiv cy_0 \pmod a$ with $|x_0| < s$ and $|y_0| < r$. Since $r = \gcd(a,b)$ and $s = \gcd(a,c)$, $bx_0 \bmod a \in \{0, r, 2r, 3r, \ldots, a-r\}$ and $cy_0 \bmod a \in \{0, s, 2s, 3s, \ldots, a-s\}$. Since $rs = a$ and $\gcd(r,s) = 1$, it follows that $bx_0 \bmod a = cy_0 \bmod a = 0$. This is only possible if $x_0 = y_0 = 0$ since $|x_0| < s$ and $|y_0| < r$, which in turn implies $x_1 = x_2$ and $y_1 = y_2$. Since $rs = a$, it follows that the set $\{bx+cy : 0 \le x \le s-1, 0 \le y \le r-1\}$ is a complete residue system modulo a.

Fix $x_0 \in \{0, \ldots, s-1\}$ and $y_0 \in \{0, \ldots, r-1\}$. We show that $bx_0+cy_0-a \notin \Gamma(\{a,b,c\})$. Suppose, to the contrary, that $bx_0+cy_0-a = az+bx+cy$ for some nonnegative integers x, y, z. Let $x = x_1 + ls$, $0 \le x_1 \le s-1$, $l \ge 0$, and $y = y_1 + \mu r$, $0 \le y_1 \le r-1$, $\mu \ge 0$. Then $bx_1+cy_1 \equiv bx+cy \equiv bx_0+cy_0 \pmod a$. By the argument in the preceding paragraph, $x_1 = x_0$ and $y_1 = y_0$. But this is clearly impossible since $bx_0+cy_0-a = az+bx+cy \ge bx+cy \ge bx_1+cy_1 = bx_0+cy_0$. Therefore $bx_0+cy_0-a \notin \Gamma(\{a,b,c\})$ for each $0 \le x_0 \le s-1$ and $0 \le y_0 \le r-1$. □

Proof of Theorem 1, (a), (b), and (c).

(a) Recall that $bs = \mathrm{lcm}(a,b)$ and $cr = \mathrm{lcm}(a,c)$. We apply Proposition 3.

$$\begin{aligned}
\mathrm{g}(a,b,c) &= \left(\max_{0\le i\le a-1} \mathbf{m}_i\right) - a \\
&= \left(\max_{0\le x\le s-1,\, 0\le y\le r-1} (bx+cy)\right) - a \\
&= b(s-1) + c(r-1) - a \\
&= \mathrm{lcm}(a,b) + \mathrm{lcm}(a,c) - (a+b+c).
\end{aligned}$$

(b)

$$\begin{aligned}
\mathrm{n}(a,b,c) &= \frac{1}{a}\sum_{i=0}^{a-1} \mathbf{m}_i - \frac{1}{2}(a-1) \\
&= \frac{1}{a}\sum_{x=0}^{s-1}\sum_{y=0}^{r-1} (bx+cy) - \frac{1}{2}(a-1) \\
&= \frac{1}{a}\sum_{x=0}^{s-1} \left(brx + \frac{1}{2}cr(r-1)\right) - \frac{1}{2}(a-1) \\
&= \frac{1}{a}\left(\frac{1}{2}brs(s-1) + \frac{1}{2}crs(r-1)\right) - \frac{1}{2}(a-1) \\
&= \frac{1}{2}\Big(b(s-1) + c(r-1)\Big) - \frac{1}{2}(a-1) \\
&= \frac{1}{2}\Big(\mathrm{lcm}(a,b) + \mathrm{lcm}(a,c) - (a+b+c) + 1\Big).
\end{aligned}$$

(c)

$$\begin{aligned}
\mathrm{s}(a,b,c) &= \frac{1}{2a}\sum_{i=0}^{a-1}\mathbf{m}_i{}^2 - \frac{1}{2}\sum_{i=0}^{a-1}\mathbf{m}_i + \frac{1}{12}(a^2-1)\\
&= \frac{1}{2a}\sum_{x=0}^{s-1}\sum_{y=0}^{r-1}(bx+cy)^2 - \frac{1}{2}\sum_{x=0}^{s-1}\sum_{y=0}^{r-1}(bx+cy) + \frac{1}{12}(a^2-1)\\
&= \frac{1}{2a}\sum_{x=0}^{s-1}\left(b^2rx^2 + bcr(r-1)x + \frac{1}{6}c^2r(r-1)(2r-1)\right) - \frac{1}{2}\sum_{x=0}^{s-1}\left(brx + \frac{1}{2}cr(r-1)\right)\\
&\quad + \frac{1}{12}(a^2-1)\\
&= \frac{1}{12a}b^2rs(s-1)(2s-1) + \frac{1}{4a}bcr(r-1)s(s-1) + \frac{1}{12a}c^2rs(r-1)(2r-1)\\
&\quad - \frac{1}{4}brs(s-1) - \frac{1}{4}crs(r-1) + \frac{1}{12}(a^2-1)\\
&= \frac{1}{12}\Big(b^2(s-1)(2s-1) + c^2(r-1)(2r-1)\Big)\\
&\quad + \frac{1}{4}\Big(bc(r-1)(s-1) - ab(s-1) - ac(r-1)\Big) + \frac{1}{12}(a^2-1)\\
&= \frac{1}{12}\Big(2\big((bs)^2 + (cr)^2\big) - 3b(bs) - 3c(cr) + b^2 + c^2 + 3abc\\
&\quad - 3bc(r+s) + 3bc + 3ab + 3ac - 3a(bs+cr) + a^2 - 1\Big)\\
&= \frac{1}{12}\Big(a^2 + b^2 + c^2 + 3abc + 3(ab+bc+ca) - 3(a+b+c)\big(\operatorname{lcm}(a,b) + \operatorname{lcm}(a,c)\big)\\
&\quad + 2\big(\big(\operatorname{lcm}(a,b)\big)^2 + \big(\operatorname{lcm}(a,c)\big)^2\big) - 1\Big).
\end{aligned}$$

□

3.3 Determining g(A), n(A) and s(A) from Proposition 4

Theorem 8 plays a crucial role in determining g(A), n(A), and s(A) using Proposition 4. In each case, however, we are only able to reduce the problem to an expression that we have already evaluated in Subsection 3.2, but not able to compute these functions directly. In effect, this is a demonstration of how the results in Proposition 3 and Proposition 4 are connected.

From Theorem 8 we know that every $n \in \Gamma(A)$ may be uniquely expressed as $bx+cy+az$,

with $x \in \{0, \ldots, s-1\}$, $y \in \{0, \ldots, r-1\}$, and $z \in \mathbb{Z}_{\geq 0}$. Hence

$$\begin{aligned} f_{\Gamma^c(A)}(t) &= \frac{1}{1-t} - f_{\Gamma(A)}(t) \\ &= \frac{1}{1-t} - \sum_{\substack{0 \leq x \leq s-1 \\ 0 \leq y \leq r-1 \\ z \geq 0}} t^{bx+cy+az} \\ &= \frac{1}{1-t} - \left(\sum_{0 \leq x \leq s-1} t^{bx} \right) \left(\sum_{0 \leq y \leq r-1} t^{cy} \right) \left(\sum_{z \geq 0} t^{az} \right) \\ &= \frac{1}{1-t} - \frac{1-t^{bs}}{1-t^b} \cdot \frac{1-t^{cr}}{1-t^c} \cdot \frac{1}{1-t^a}. \end{aligned}$$

However, it is perhaps more useful to use the equivalent formulation

$$f_{\Gamma^c(A)}(t) = \frac{1}{1-t^a} \left(\sum_{0 \leq z \leq a-1} t^z - \sum_{\substack{0 \leq x \leq s-1 \\ 0 \leq y \leq r-1}} t^{bx+cy} \right)$$

to see how the computation of $\mathrm{g}(A)$ and $\mathrm{n}(A)$ would follow from Proposition 4 and Theorem 8. Deriving the formulae for $\mathrm{g}(A)$, $\mathrm{n}(A)$, and $\mathrm{s}(A)$ directly from either of the two equivalent versions of $f_{\Gamma^c(A)}(t)$ appear to be difficult; instead, we use Proposition 4 to reduce the respective formulae to the situation in Subsection 3.2. The reduction of the formula for $\mathrm{s}(A)$ in Proposition 4 to that in Proposition 3 in this special case is tedious, and is omitted in this discussion.

(a)

$$\mathrm{g}(a,b,c) = \deg \left(\frac{1}{1-t} - \sum_{\substack{0 \leq x \leq s-1 \\ 0 \leq y \leq r-1 \\ z \geq 0}} t^{bx+cy+az} \right) = \max \Gamma^c(A) = \left(\max_{\mathbf{C}} \mathbf{m}_{\mathbf{C}} \right) - a.$$

(b)

$$\begin{aligned}
\mathrm{n}(a,b,c) &= \lim_{t\to 1}\frac{1}{1-t^a}\left(\sum_{0\le z\le a-1} t^z - \sum_{\substack{0\le x\le s-1\\ 0\le y\le r-1}} t^{bx+cy}\right)\\
&= \lim_{t\to 1}\frac{1}{-at^{a-1}}\left(\sum_{1\le z\le a-1} zt^{z-1} - \sum_{\substack{0\le x\le s-1\\ 0\le y\le r-1\\ (x,y)\neq(0,0)}} (bx+cy)t^{bx+cy-1}\right)\\
&= \frac{1}{a}\left(\sum_{\substack{0\le x\le s-1\\ 0\le y\le r-1\\ (x,y)\neq(0,0)}} (bx+cy) - \sum_{1\le z\le a-1} z\right)\\
&= \frac{1}{a}\sum_{\mathbf{C}} \mathbf{m_C} - \frac{1}{2}(a-1).
\end{aligned}$$

□

3.4 Deriving $\mathrm{n}(A)$ from $\mathrm{g}(A)$

The results of Theorems 1 imply $n \in \Gamma(\{a,b,c\})$ if and only if $\mathrm{g}(a,b,c)-n \notin \Gamma(\{a,b,c\})$. Were this to hold, it would follow by pairing n with $\mathrm{g}(a,b,c)-n$ for $n \in \{0,\ldots,\mathrm{g}(a,b,c)\}$ that

$$\mathrm{n}(a,b,c) = \tfrac{1}{2}\big(\mathrm{g}(a,b,c)+1\big).$$

Thus the formula for $\mathrm{n}(a,b,c)$ would follow from that of $\mathrm{g}(a,b,c)$, and vice-versa, in this case.

It is easy to see that at least one of n and $\mathrm{g}(a,b,c)-n$ must belong to $\Gamma^c(\{a,b,c\})$; if both belonged to $\Gamma(\{a,b,c\})$, it would lead to their sum $\mathrm{g}(a,b,c)$ belonging to $\Gamma(\{a,b,c\})$. Therefore we always have the inequality

$$\mathrm{n}(a,b,c) \ge \tfrac{1}{2}\big(\mathrm{g}(a,b,c)+1\big),$$

with equality precisely when

$$n \notin \Gamma(\{a,b,c\}) \text{ implies } \mathrm{g}(a,b,c)-n \in \Gamma(\{a,b,c\})$$

holds.

Suppose $n \notin \Gamma(\{a,b,c\})$. Then $n = bx+cy-az$ for some $x \in [0,s-1]$, $y \in [0,r-1]$, and $z \ge 1$ by Theorem 8. Hence

$$\mathrm{g}(a,b,c)-n = b(s-1)+c(r-1)-a-(bx+cy-az) = b(s-1-x)+c(r-1-y)+a(z-1) \in \Gamma(\{a,b,c\}).$$

Therefore $\mathrm{n}(a,b,c) = \frac{1}{2}\big(\mathrm{g}(a,b,c)+1\big)$ holds for $A=\{a,b,c\}$ with $a \mid \mathrm{lcm}(b,c)$.

3.5 Determining the set $\mathcal{S}^\star(A)$

Determining the set $\mathcal{S}^\star(A)$ is dependent on being able to compute each $\mathbf{m_C}$. Since Theorem 8 determines the set of all $\mathbf{m_C}$, we may use Proposition 6 to determine $\mathcal{S}^\star(A)$, which in turn gives us $\mathrm{g}(A)$.

Proof of Theorem 1 (d).
Each $\mathbf{m_C}$ is of the form $bx + cy$ with $0 \le x \le s-1$ and $0 \le y \le r-1$ by Theorem 8 (a); note that $\mathbf{m}_0 = 0$. Note that $bx_1 + bx_2 \equiv b\big((x_1+x_2) \bmod s\big) \pmod a$ since $bs = \mathrm{lcm}(a,b)$ and $cy_1 + cy_2 \equiv c\big((y_1+y_2) \bmod r\big) \pmod a$ since $cr = \mathrm{lcm}(a,c)$. So if $\mathbf{m}_i = bx_1 + cy_1$ and $\mathbf{m}_j = bx_2 + cy_2$, then $\mathbf{m}_{i+j} = b\big((x_1+x_2) \bmod s\big) + c\big((y_1+y_2) \bmod r\big)$.

Although it is apparent from the definition of $\mathcal{S}^\star(A)$ that $\mathrm{g}(A) \in \mathcal{S}^\star(A)$, we nevertheless provide a direct proof using Proposition 6. We recall that $\mathrm{lcm}(a,b) = bs$ and $\mathrm{lcm}(a,c) = cr$, so that $\mathrm{g}(A) = \mathrm{lcm}(a,b) + \mathrm{lcm}(a,c) - (a+b+c) = b(s-1) + c(r-1) - a$.

Let $x \in \{0,\dots,s-1\}$ and $y \in \{0,\dots,r-1\}$, with $(x,y) \ne (0,0)$. If $x > 0$ and $y > 0$, then

$$\big(b(s-1)+c(r-1)\big)+(bx+cy) = b(x-1)+c(y-1)+\mathrm{lcm}(a,b)+\mathrm{lcm}(a,c) \ge b(x-1)+c(y-1)+2a.$$

If $x = 0$, then $y > 0$ and

$$\big(b(s-1)+c(r-1)\big)+(bx+cy) = b(s-1)+c(y-1)+\mathrm{lcm}(a,c) \ge b(s-1)+c(y-1)+a.$$

If $y = 0$, then $x > 0$ and

$$\big(b(s-1)+c(r-1)\big)+(bx+cy) = b(x-1)+c(r-1)+\mathrm{lcm}(a,b) \ge b(x-1)+c(r-1)+a.$$

Hence $b(s-1)+c(r-1)-a \in \mathcal{S}^\star$ by Proposition 6.

Suppose $x_0 \in [0, s-1]$ and $y_0 \in [0, r-1]$, with $(x_0,y_0) \ne (0,0), (s-1,r-1)$. Then $b(s-1-x_0)+c(r-1-y_0)$ is of form $\mathbf{m}_x$ and

$$(bx_0+cy_0)+b(s-1-x_0)+c(r-1-y_0) = b(s-1)+c(r-1),$$

so that Proposition 6 fails to hold for at least one $x \in [1, a-1]$. Hence $bx_0+cy_0-a \notin \mathcal{S}^\star$ if $(x_0,y_0) \ne (s-1,r-1)$.

This completes the proof of this theorem. □

Remark 9. For any set of positive integers A with $\gcd A = 1$, it can be shown that $\mathrm{n}(A) = \frac{1}{2}\big(1+\mathrm{g}(A)\big)$ implies $\mathcal{S}^\star(A) = \{\mathrm{g}(A)\}$.

Remark 10. The results of this paper cannot be easily extended to the case $A = \{a, b_1, \dots, b_k\}$ where $\gcd(a, b_1, \dots, b_k) = 1$ and $a \mid \mathrm{lcm}(b_1, \dots, b_k)$ for $k > 2$. This is because the divisibility condition $a \mid \mathrm{lcm}(b_1, \dots, b_k)$ does not imply $a = r_1 \cdots r_k$ where $r_i = \gcd(a, b_i)$ for $1 \le i \le k$.
