Abstract. In the present work we review the twisted field construction of quantum field theory on noncommutative spacetimes based on twisted Poincaré invariance. We present the latest development in the field, in particular the notion of equivalence of such quantum field theories on a noncommutative spacetime, in this regard we work out explicitly the inequivalence between twisted quantum field theories on Moyal and Wick–Voros planes; the duality between deformations of the multiplication map on the algebra of functions on spacetime $\mathscr{F}(\mathbb{R}^4)$ and coproduct deformations of the Poincaré–Hopf algebra $H\mathscr{P}$ acting on $\mathscr{F}(\mathbb{R}^4)$; the appearance of a nonassociative product on $\mathscr{F}(\mathbb{R}^4)$ when gauge fields are also included in the picture. The last part of the manuscript is dedicated to the phenomenology of noncommutative quantum field theories in the particular approach adopted in this review. CPT violating processes, modification of two-point temperature correlation function in CMB spectrum analysis and Pauli-forbidden transition in Be^4 are all effects which show up in such a noncommutative setting. We review how they appear and in particular the constraint we can infer from comparison between theoretical computations and experimental bounds on such effects. The best bound we can get, coming from Borexino experiment, is $\gtrsim 10^{24}$ TeV for the energy scale of noncommutativity, which corresponds to a length scale $\lesssim 10^{-43}$ m. This bound comes from a different model of spacetime deformation more adapted to applications in atomic physics. It is thus model dependent even though similar bounds are expected for the Moyal spacetime as well as argued elsewhere.

Key words: noncommutative spacetime; quantum field theory; twisted field construction; Poincaré–Hopf algebra

2010 Mathematics Subject Classification: 81R50; 81R60

1 Introduction

A great deal of effort has been put in trying to achieve a formulation of a theory of quantum gravity.

It has long been speculated that spacetime structure changes radically at Planck scales. In 1994, in a fundamental paper, Doplicher, Fredenhaghen and Roberts argued that the commu-

---

tator among the four spacetime coordinates of a physical theory in which Einstein's theory of relativity and principles of Quantum Mechanics both coexist, should not vanish[1] [1]. This argument suggested that noncommutativity of spacetime at Planck scales, a feature seen before as just a way to regularize quantum field theory, is possibly one of the main features of quantum gravity. We will now sketch the argument, for further details we refer to the original papers [1, 3].

From quantum physics we know that to probe a spacetime region with radius of the order of the Planck length

$$L_P = \sqrt{\frac{G\hbar}{c^3}} \simeq 1.6 \times 10^{-33} \text{ cm},$$

we need a particle of mass M^* such that its Compton wavelength is smaller than the length scale of the spacetime region we wish to probe, namely of the Planck length:

$$\lambda_C = \frac{\hbar}{M^*c} \leq L_P \quad \Rightarrow \quad M^* \geq \frac{\hbar}{L_P c} \simeq 10^{19} \text{ Gev}.$$

Einstein's theory of relativity tells us that the Schwarzschild radius associated to such a mass distribution is

$$R_S = \frac{2GM^*}{c^2} \geq 2L_P.$$

It is thus greater than the region we would like to explore. Thus probing spacetime at the Planck scale generates a paradox: in the process an event horizon (or a trapped surface) is created which now prevents us to access altogether the spacetime region we were initially interested in.

In order to avoid the collapse of the probed region, we must assume that it is not possible to simultaneously measure all four spacetime coordinates. This requirement can be incorporated in the noncommutativity of coordinates. A simple choice for this noncommutativity is

$$[\widehat{x}_\mu, \widehat{x}_\nu] = i\theta_{\mu\nu}. \tag{1.1}$$

Here $\theta_{\mu\nu} = -\theta_{\nu\mu}$ are constants and $\widehat{x}_\mu$ are the coordinate functions on an n-dimensional spacetime $\mathbb{R}^n$ on which the Poincaré group acts in a standard manner for $\theta_{\mu\nu} = 0$:

$$\widehat{x}_\mu(x) = x_\mu.$$

In the present paper, the relations (1.1) will be assumed. We will describe how to formulate the minimal requirements for a quantum field theory (QFT) on such a spacetime and two particular instances of quantum field theories will be constructed over such noncommutative spacetimes, the Moyal and the Wick–Voros quantum fields. We should point it out here that different proposals have been discussed in the literature (see for instance [12, 13] and references therein), however the construction provided here is constructive and their consistency and properties can be tested directly. The paper will be organised as follows. In the next section we will introduce the Drinfel'd twist and the deformation of the Poincaré Hopf algebra $H\mathscr{P}$. Both concepts will play a crucial role in the formulation of QFT on noncommutative spacetime, which will be then explained in Section 3. Relations (1.1) do not uniquely specify the spacetime algebra. For example, both Moyal and Wick–Voros planes are compatible with (1.1). In Sections 4 and 5 we will see how this freedom gets reflected on the QFT side. In Section 6 we will present some further mathematical developments while the last section will be devoted to describe phenomenological consequences of noncommutative spacetimes. They influence the

---

[1]The idea of extra-dimensions has been widely used recently. Even in those cases the description of spacetime in terms of a four dimensional manifold must be achieved in some sort of effective limit. It has been shown that the four dimensional limit of certain string theories [2] does, in fact, involve a noncommutative spacetime.

cosmic microwave background, the K^0–$\bar{K}^0$ mass difference and the Pauli principle among others. From available data we will present the experimental bounds on the scale of spacetime noncommutativity. The best bound we find for its energy scale is $\gtrsim 10^{24}$ TeV. It comes from Borexino and Superkamiokande experiments. We will then conclude with some final remarks.

2 The Drinfel'd twist and deformed coproduct

At first we notice that the relations (1.1) can be implemented by deforming the product of the standard commutative algebra of functions on our n-dimensional space-time $\mathcal{A}_0 \equiv (\mathscr{F}(\mathcal{M}), m_0)$, where $\mathcal{M} \cong \mathbb{R}^n$, $\mathscr{F}(\mathcal{M})$ are smooth functions on $\mathcal{M}$ and m_0 is the point-wise multiplication map:

$$m_0(f \otimes g)(x) = f(x)g(x) = g(x)f(x) = m_0(g \otimes f)(x).$$

There is a general procedure to deform such a product in a controlled way using the so-called *twist deformation* [4].

Let us denote as $\mathcal{A}_\theta = (\mathscr{F}(\mathcal{M}), m_\theta)$ such a deformation of $\mathcal{A}_0$ which leads to (1.1). Here $m_\theta = m_0 \circ \mathcal{F}_\theta$ is a noncommutative product and $\mathcal{F}_\theta$ the *twist map*. The two satisfy:

$$m_\theta(f \otimes g)(x) = m_0 \circ \mathcal{F}_\theta(f \otimes g)(x) := (f \star g)(x), \tag{2.1}$$
$$\mathcal{F}_\theta: \ \mathscr{F}(\mathcal{M}) \otimes \mathscr{F}(\mathcal{M}) \to \mathscr{F}(\mathcal{M}) \otimes \mathscr{F}(\mathcal{M)} \qquad \text{and} \qquad \mathcal{F}_\theta \to \mathbb{1} \quad \text{as} \quad \theta \to 0.$$

An explicit form of $\mathcal{F}_\theta$ is

$$\mathcal{F}_\theta = \exp \frac{i}{2}\theta[\partial_x \otimes \partial_y - \partial_y \otimes \partial_x]. \tag{2.2}$$

In particular the unit is preserved by the deformation. We notice that

1) $\mathcal{F}_\theta$ is one-to-one and invertible;

2) $\mathcal{F}_\theta$ acts on the tensor product in a non-factorizable manner, i.e. the action on $\mathscr{F}(\mathcal{M}) \otimes \mathscr{F}(\mathcal{M})$ intertwines the two factors.

The above choice of $\mathcal{F}_\theta \equiv \mathcal{F}_\theta^{\mathcal{M}}$ leads to the Moyal plane $\mathcal{A}_\theta^{\mathcal{M}}$:

$$m_\theta^{\mathcal{M}}(f \otimes g)(x,y) \equiv f(x,y) \cdot g(x,y) + \frac{i}{2}\theta\big[(\partial_x f)(\partial_y g) - (\partial_y f)(\partial_x g)\big]$$
$$+ \sum_{n=2} \frac{\big[\frac{i}{2}\theta(\partial_x \otimes \partial_y - \partial_y \otimes \partial_x)\big]^n}{n!}(f \otimes g).$$

But it is not unique. Another choice, leading to the Voros plane $\mathcal{A}_\theta^V$ is

$$\mathcal{F}_\theta^V = \exp \frac{1}{2}\theta[\partial_x \otimes \partial_x + \partial_y \otimes \partial_y]\mathcal{F}_\theta^{\mathcal{M}} = \mathcal{F}_\theta^{\mathcal{M}} \exp \frac{1}{2}\theta[\partial_x \otimes \partial_x + \partial_y \otimes \partial_y]. \tag{2.3}$$

The noncommutative relations (1.1) bring with them another problem: at first sight it seems that the noncommutativity of spacetime coordinates violates Poincaré invariance: the l.h.s. of (1.1) transforms in a non-trivial way under the standard action of the Poincaré group $\mathscr{P}$ whereas the r.h.s. does not. But there is still a way to act properly with the Poincaré group, or rather, with its group algebra $\mathbb{C}\mathscr{P}$, on the deformed algebras $\mathcal{A}_\theta$ if its action is changed to the so-called twisted action [5, 6, 7]. It goes as follows. The l.h.s. of (1.1) is an element of the tensor product space followed by $m_\theta: \mathcal{A}_\theta^{\mathcal{M},V} \otimes \mathcal{A}_\theta^{\mathcal{M},V} \to \mathcal{A}_\theta^{\mathcal{M},V}$. The way in which $\mathbb{C}\mathscr{P}$ acts on the tensor product space requires a homomorphism $\mathbb{C}\mathscr{P} \to \mathbb{C}\mathscr{P} \otimes \mathbb{C}\mathscr{P}$. It is not fixed by the

way $\mathscr{P}$ acts on $\mathcal{A}_\theta$, but is a further ingredient of the theory we need to specify. This map is called the coproduct and will be denoted by Δ:

$$\Delta : \; \mathbb{C}\mathscr{P} \to \mathbb{C}\mathscr{P} \otimes \mathbb{C}\mathscr{P}.$$

Once we provide $\mathbb{C}\mathscr{P}$ with the coproduct Δ, that is we also specify how $\mathbb{C}\mathscr{P}$ acts on a tensor product space, we get a new mathematical structure called a Hopf algebra $H\mathscr{P}$. There are further formal compatibility requirements between the multiplication map of $\mathbb{C}\mathscr{P}$ and the map Δ, but we will not discuss them here. For further details on Hopf algebras, we refer to [8, 9, 10, 11].

Usually we assume for the coproduct the simple separable map Δ_0:

$$\Delta_0(g) = g \otimes g \qquad \forall\, g \in \mathscr{P}. \tag{2.4}$$

It extends to $\mathbb{C}\mathscr{P}$ by linearity. But (2.4) is not the only possible choice. The idea proposed in [5, 6, 7] is that we can assume a different coproduct on $\mathbb{C}\mathscr{P}$, that is "twisted" or deformed with respect to Δ_0, to modify the action of the Poincaré group on tensor product spaces in such a way that it does preserve relations (1.1). We must realize here that the change of Δ_0 is not a mere mathematical construction, as it affects the way composite systems transform under spacetime symmetries. This observation will have deep consequences in the physical interpretation of the theory as it will be shown later. This modification changes the standard Hopf algebra structure associated with the Poincaré group (the Poincaré–Hopf algebra $H\mathscr{P}$) to a twisted Poincaré–Hopf algebra $H_\theta\mathscr{P}$ ($H_0\mathscr{P} \equiv H\mathscr{P}$).

The deformed algebra is not unique. For the Moyal and Wick–Voros cases they are different, although isomorphic[2]. The isomorphism map is

$$\gamma = \mathrm{e}^{-\frac{1}{4}\theta(\partial_x^2 + \partial_y^2)}, \qquad \gamma : \; \mathcal{A}_\theta^{\mathcal{M}} \to \mathcal{A}_\theta^{V} \qquad \text{and} \qquad \mathcal{F}_\theta^{V} = \gamma \otimes \gamma \mathcal{F}_\theta^{\mathcal{M}} \Delta\big(\gamma^{-1}\big).$$

We denote them by $H_\theta^{\mathcal{M},V}\mathscr{P}$ when we want to emphasise that we are working with Moyal and Wick–Voros spacetimes.

Still they lead to different QFT's since the isomorphism map is not unitary. We discuss this point in detail in Sections 4 and 5.

The explicit form of the deformed coproduct Δ_θ of $H_\theta\mathscr{P}$ is obtained from requiring that the action of $\mathbb{C}\mathscr{P}$ is an *automorphism* of the new algebra of functions $\mathcal{A}_\theta$ on spacetime. That is, the action of $\mathbb{C}\mathscr{P}$ has to be compatible with the new noncommutative multiplication rule (2.1). In particular, for $g \in \mathscr{P} \subset \mathbb{C}\mathscr{P}$,

$$g \triangleright m_\theta(f \otimes h)(x) = m_\theta(g \triangleright (f \otimes h))(x).$$

It is easy to see that the standard coproduct choice (2.4) is not compatible [5, 6, 7] with the action of $\mathbb{C}\mathscr{P}$ on the deformed algebra $\mathcal{A}_\theta$. In the cases under consideration, where $\mathcal{A}_\theta$ are twist deformations of $\mathcal{A}_0$, there is a simple rule to get deformations Δ_θ of Δ_0 compatible with m_θ. They are given by the formula:

$$\Delta_\theta = (F_\theta)^{-1} \Delta_0 F_\theta, \tag{2.5}$$

where F_θ is an element in $H_\theta\mathscr{P} \otimes H_\theta\mathscr{P}$ and it is determined by the map $\mathcal{F}_\theta$ introduced before, $\mathcal{F}_\theta$ being the realisation of F_θ on $\mathcal{A}_\theta \otimes \mathcal{A}_\theta$.

For $\mathcal{F}_\theta = \mathcal{F}_\theta^{\mathcal{M},V}$, the corresponding $F_\theta^{\mathcal{M},V}$ give us the Hopf algebras $H_\theta^{\mathcal{M},V}\mathscr{P}$.

Without going deeper into the deformation theory of Hopf algebras, we just note that the deformations we are considering here are very specific ones since we keep the multiplication rules

---

[2]The two deformations are in fact equivalent in Hopf algebra deformation theory. That is they belong to the same equivalence class in the non-Abelian cohomology that classifies Hopf algebra twist-deformations. See for details [10].

unchanged and deform only the co-structures of the underlying Hopf algebra. Thus for $\mathbb{C}\mathscr{P}$, we only change Δ_0 to Δ_θ leaving the group multiplication the same. For a deeper discussion on deformations of algebras and Hopf algebras, we refer again to the literature [8, 9, 10, 11].

Lastly we have to introduce the concept of twisted statistics. It is a strict consequence of the twisted action of the Poincaré group on the tensor product space (2.5). In quantum mechanics two kinds of particles, with different statistics, are admitted: fermions, which are described by fully antisymmetrised states, and bosons, which are instead completely symmetric. Let $\mathcal{H}$ be a single particle Hilbert space. Then given a two-particle quantum state, $\alpha \otimes \beta$ with $\alpha, \beta \in \mathcal{H}$, we can get its symmetrised and anti-symmetrised parts as:

$$\alpha \otimes_{S,A} \beta = \frac{\mathbb{1} \pm \tau_0}{2} \alpha \otimes \beta,$$

where the map τ_0 is called the *flip operator* and it simply switches the elements on which it acts,

$$\tau_0(\alpha \otimes \beta) = \beta \otimes \alpha.$$

From the foundations of quantum field theories it can be proved that the statistics of particles have to be superselected, that is Poincaré transformations cannot take bosons (fermions) into fermions (bosons). In other words, a symmetric (antisymmetric) state must still be symmetric (antisymmetric) after the action of any element of the Poincaré group. This requirement implies that the flip operator has to commute with the coproduct of any element of $\mathbb{C}\mathscr{P}$. As can be trivially checked, the action of τ_0 commutes with the coproduct $\Delta_0(g)$ of $g \in \mathscr{P}$, but not with $\Delta_\theta(g)$. If we do not modify the flip operator, we end up with a theory in which, for example, a rotation can transform a fermion into a boson.

If the deformation of the coproduct is of the kind we have been considering so far, that is a twist deformation as in (2.5), again it is easy to find a deformation τ_θ of the flip operator τ_0 which commutes with Δ_θ:

$$\tau_0 \to \tau_\theta = (F_\theta)^{-1} \tau_0 F_\theta \tag{2.6}$$

and, moreover $\tau_\theta^2 = I$. This equation contains the $\mathcal{R}$-matrix of a quasi-triangular Hopf algebra. By definition, $\mathcal{R}$ is given by

$$\tau_\theta = \mathcal{R} \circ \tau_0. \tag{2.7}$$

Hence:

$$\mathcal{R} := F_\theta^{-1} \circ F_{\theta 21}, \qquad F_{\theta 21} \equiv \tau_0 F_\theta \tau_0^{-1}. \tag{2.8}$$

In quantum physics on a noncommutative spacetime, we then consider symmetrisation (anti-symmetrisation) with respect to τ_θ rather then τ_0:

$$\alpha \otimes_{S_\theta, A_\theta} \beta = \frac{\mathbb{1} \pm \tau_\theta}{2} \alpha \otimes \beta. \tag{2.9}$$

3 Examples: Moyal and Wick–Voros planes

The preceding section explains the general features of the formalism of deformations of algebras induced by the relations (1.1) and how to deform the Hopf algebra structure of the Poincaré group to keep the theory still invariant under its action, as in (2.5). We now proceed with the study of two explicit examples: Moyal and Wick–Voros planes.

As previously indicated, we denote by $\mathcal{F}_\theta^{\mathcal{M},V}$ and $m_\theta^{\mathcal{M},V}$ the twists and multiplication maps for the deformed algebras $\mathcal{A}_\theta^{\mathcal{M},V}$ respectively. Then as in (2.1)

$$m_\theta^{\mathcal{M},V}(f \otimes g) \equiv m_0 \circ \mathcal{F}_\theta^{\mathcal{M},V}(f \otimes g). \tag{3.1}$$

In the following, for the sake of simplicity, we will work in two dimensions. The generalization to arbitrary dimensions will be discussed in Section 7.

In two dimensions, we can always write $\theta_{\mu\nu}$ as

$$\theta_{\mu\nu} = \theta\epsilon_{\mu\nu}, \qquad \epsilon_{01} = -\epsilon_{10} = 1, \tag{3.2}$$

where θ is a constant. Then as in (2.2) and (2.3) the two twists $\mathcal{F}_\theta^{\mathcal{M},V}$ assume the form

$$\mathcal{F}_\theta^{\mathcal{M}} = \exp\frac{i}{2}\theta[\partial_x \otimes \partial_y - \partial_y \otimes \partial_x],$$

$$\mathcal{F}_\theta^{V} = \exp\frac{1}{2}\theta[\partial_x \otimes \partial_x + \partial_y \otimes \partial_y]\mathcal{F}_\theta^{\mathcal{M}} = \mathcal{F}_\theta^{\mathcal{M}}\exp\frac{1}{2}\theta[\partial_x \otimes \partial_x + \partial_y \otimes \partial_y]. \tag{3.3}$$

Hereafter we will call $\mathcal{F}_\theta^{\mathcal{M}}$ and $\mathcal{F}_\theta^{V}$ the Moyal and Wick–Voros twists, and $\mathcal{A}_\theta^{\mathcal{M}}$ and $\mathcal{A}_\theta^{V}$ the Moyal and Wick–Voros algebras respectively. Both deformations, $\mathcal{A}_\theta^{\mathcal{M}}$ and $\mathcal{A}_\theta^{V}$, realize the commutation relations (1.1). This fact already shows, as pointed out above, how noncommutativity of spacetime does not fix uniquely the deformation of the algebra. There are many more noncommutative algebras of functions on spacetime that realize (1.1) with different twisted products. In order to address the study of how this freedom reflects on the quantum field theory side it is enough to work with two of them. Thus hereafter we will only work with $\mathcal{A}_\theta^{\mathcal{M},V}$.

Given the above expressions for the twists, explicit expressions for the noncommutative product of the functions in the two cases follow immediately from (3.1):

$$(f \star_{\mathcal{M}} g)(x) = m_\theta^{\mathcal{M}}(f \otimes g)(x) \equiv f(x)e^{\frac{i}{2}\theta_{\alpha\beta}\overleftarrow{\partial^\alpha}\otimes\overrightarrow{\partial^\beta}}g(x), \tag{3.4}$$

$$(f \star_{V} g)(x) = m_\theta^{V}(f \otimes g)(x) \equiv f(x)e^{\frac{i}{2}\left(\theta_{\alpha\beta}\overleftarrow{\partial^\alpha}\otimes\overrightarrow{\partial^\beta}-i\theta\delta_{\alpha\beta}\overleftarrow{\partial^\alpha}\otimes\overrightarrow{\partial^\beta}\right)}g(x).$$

If we let the $\star$-product to act on the coordinate functions, we get in both cases the noncommutative relations (1.1).

Once the two twists are given, following (2.5), we can immediately write down the deformations of the two coproducts as well:

$$\Delta_\theta^{\mathcal{M},V}(g) = \left(F_\theta^{\mathcal{M},V}\right)^{-1}\Delta_0(g)F_\theta^{\mathcal{M},V} = \left(F_\theta^{\mathcal{M},V}\right)^{-1}(g \otimes g)F_\theta^{\mathcal{M},V}. \tag{3.5}$$

Here $F_\theta^{\mathcal{M},V} \in H\mathscr{P} \otimes H\mathscr{P}$ are:

$$F_\theta^{\mathcal{M}} = \exp\left(-\frac{i}{2}\theta[P_x \otimes P_y - P_y \otimes P_x]\right), \tag{3.6}$$

$$F_\theta^{V} = \exp\left(-\frac{1}{2}\theta[P_x \otimes P_x + P_y \otimes P_y]\right)F_\theta^{\mathcal{M}} = F_\theta^{\mathcal{M}}\exp\left(-\frac{1}{2}\theta[P_x \otimes P_x + P_y \otimes P_y]\right),$$

where P_μ are translation generators. Their realisation on $\mathcal{A}_\theta^{\mathcal{M},V}$ is:

$$P_\mu \triangleright f(x) \equiv (P_\mu f)(x) = -i(\partial_\mu f)(x).$$

We end this section with a discussion on how the τ_0 gets twisted in the two cases. As $F_\theta^{\mathcal{M}}$ is skew-symmetric and F_θ^{V} is the composition of $F_\theta^{\mathcal{M}}$ and a symmetric part, we get:

$$F_{\theta 21}^{\mathcal{M}} = \left(F_\theta^{\mathcal{M}}\right)^{-1},$$

$$F_{\theta 21}^V = \exp\left(-\frac{1}{2}\theta[P_x \otimes P_x + P_y \otimes P_y]\right)\left(F_\theta^{\mathcal{M}}\right)^{-1}.$$

In the $\mathcal{R}$-matrix (2.8), any symmetric part of the twist cancels. Thus in both Moyal and Wick–Voros cases, the statistics of particles is twisted in the same way:

$$\mathcal{R}^{\mathcal{M},V} = \left(F_\theta^{\mathcal{M}}\right)^{-2} = \exp\left(-i\theta[P_x \otimes P_y - P_y \otimes P_x]\right).$$

We must point out here that the results discussed in this paper differ from those in [12] because of the differences in the construction of quantum field theories on $\mathcal{A}_\theta^{\mathcal{M},V}$ here and in [13]. Thus while our approach is based on Hilbert spaces, operators and explicitly enforces unitarity, the other approach uses functional integrals. There are issues to be clarified in the case of functional integrals in the context of the Moyal plane as they do not fulfill reflection positivity. For a detailed discussion of this issue, see [14].

4 Quantum field theories on Moyal and Voros planes

It is time now to discuss how to quantize the two theories introduced in the previous section. Our approach to the Moyal plane is discussed in [7, 15] and to the Wick–Voros plane can be found in [16, 17]. For another approach to the latter, see [12].

The quantization procedure consists in finding a set of creation operators, and by adjointness the annihilation counterpart, which create multiparticle states providing a unitary representation of the twisted Poincaré–Hopf symmetry. Such a set of creation and annihilation operators must also implement the appropriate twisted statistics (2.7)–(2.9). Out of them we can construct the twisted quantum fields (QFs). It has been in fact proven elsewhere [7, 15] that the Hamiltonian constructed out of such twisted fields is Hopf–Poincaré invariant.

Let us first consider the Moyal case. As our previous work [7, 15] shows,

$$a_p^{\mathcal{M}} = c_p \exp\left(-\frac{i}{2}p_\mu\theta^{\mu\nu}P_\nu\right), \tag{4.1}$$

$$a_p^{\mathcal{M}\dagger} = c_p^\dagger \exp\left(\frac{i}{2}p_\mu\theta^{\mu\nu}P_\nu\right), \tag{4.2}$$

where c_p, $c_p^\dagger$ are the untwisted $\theta^{\mu\nu} = 0$ annihilation and creation operators (we can assume all such operators to refer to in-, out- or free-operators as the occasion demands), provide the operators we were looking for. Let's see that.

Since we are considering only deformations in which the coproduct is changed, the way in which the Poincaré group acts on a single particle state is the usual one. Therefore the creation operator (4.2) on the vacuum will act like the untwisted operator $c_p^\dagger$. It is then plausible that the generators of Poincaré transformations on the Hilbert space under consideration have to be the untwisted ones. We will now confirm this: if $(a, \Lambda) \to U(a, \Lambda) \equiv U(\Lambda)U(a)$ is the $\theta = 0$ unitary representation of the Poincaré group, we will show that the multiparticle states created by acting with (4.2) on the vacuum transform with the Moyal coproduct (3.5).

If we consider the action of a general group element of the Poincaré group (a, Λ) on a two-particle state $|p, q\rangle_\theta$, we expect

$$\Delta_\theta^{\mathcal{M}}\big((a, \Lambda)\big) \triangleright |p, q\rangle_\theta = \left(F_\theta^{\mathcal{M}}\right)^{-1}\big((a, \Lambda) \otimes (a, \Lambda)\big)F_\theta^{\mathcal{M}} \triangleright |p, q\rangle_\theta$$
$$= |\Lambda p, \Lambda q\rangle_\theta e^{-\frac{i}{2}(p \wedge q - \Lambda p \wedge \Lambda q)} e^{-i(p+q)\cdot a}, \tag{4.3}$$

where $a \wedge b := a_\mu\theta^{\mu\nu}b_\nu$, and we have used the properties of a momentum eigenstate, $P_\mu \triangleright |p\rangle = p_\mu|p\rangle$ and $(a, \Lambda) \triangleright |p\rangle = |\Lambda p\rangle e^{-ip\cdot a}$.

For the $\theta = 0$ generators of the unitary representation of the Poincaré group on the Hilbert space under consideration, we have

$$U(a, \Lambda)c_p^\dagger U^{-1}(a, \Lambda) = \mathrm{e}^{ip \cdot a} c_{\Lambda p}^\dagger.$$

Defining [22][3]

$$|p, q\rangle_\theta^{\mathcal{M}} = a_q^{\mathcal{M}\dagger} a_p^{\mathcal{M}\dagger}|0\rangle \tag{4.4}$$

we can now explicitly compute how $U(a, \Lambda)$ acts on the two-particle state considered in (4.4):

$$U(a, \Lambda)|p, q\rangle_\theta = U(a, \Lambda)c_q^\dagger U^{-1}(a, \Lambda)U(a, \Lambda)\mathrm{e}^{\frac{i}{2}q \wedge P}c_p^\dagger|0\rangle = c_{\Lambda q}^\dagger c_{\Lambda p}^\dagger|0\rangle \mathrm{e}^{-i(p+q) \cdot a} \mathrm{e}^{\frac{i}{2}q \wedge p}$$

$$= a_{\Lambda q}^{\mathcal{M}\dagger} \mathrm{e}^{\frac{i}{2}q \wedge P}c_{\Lambda p}^\dagger|0\rangle \mathrm{e}^{\frac{i}{2}q \wedge p}\mathrm{e}^{-i(p+q) \cdot a} = |\Lambda p, \Lambda q\rangle \mathrm{e}^{-\frac{i}{2}(p \wedge q - \Lambda p \wedge \Lambda q)}\mathrm{e}^{-i(p+q) \cdot a}. \tag{4.5}$$

In the above computation we have used $P_\nu|0\rangle = 0$ and a relation which will be used repeatedly in what follows: $\mathrm{e}^{\frac{i}{2}p_\mu \theta^{\mu\nu}P_\nu}c_q^\dagger \mathrm{e}^{-\frac{i}{2}p_\mu \theta^{\mu\nu}P_\nu} = \mathrm{e}^{\frac{i}{2}p_\mu \theta^{\mu\nu}[P_\nu, \cdot]}c_q^\dagger = \mathrm{e}^{\frac{i}{2}p_\mu \theta^{\mu\nu}q_\nu}c_q^\dagger$. Thus (4.5) coincides with (4.3). It is a remarkable fact that the appropriate deformation of the coproduct naturally appears as the $\theta = 0$ Poincaré group generator acts on the two particle states obtained by the creation operator (4.2). This result generalises to n-particles states.

The two-particle state in (4.3) also fulfills the twisted statistics. From (2.7), (2.9) we expect that (throughout this paper we will only consider the bosonic case):

$$|p, q\rangle_\theta^{\mathcal{M}} = \frac{\mathbb{1} + \tau_\theta^{\mathcal{M}}}{2}|p, q\rangle = \frac{1}{2}\left(|p, q\rangle + \mathrm{e}^{-i\vec{q} \wedge \vec{p}}|q, p\rangle\right)$$

and

$$|q, p\rangle_\theta^{\mathcal{M}} = \frac{\mathbb{1} + \tau_\theta^{\mathcal{M}}}{2}|q, p\rangle = \frac{1}{2}\left(|q, p\rangle + \mathrm{e}^{-i\vec{p} \wedge \vec{q}}|p, q\rangle\right) = \mathrm{e}^{-i\vec{q} \wedge \vec{p}}|p, q\rangle_\theta^{\mathcal{M}}.$$

On the other hand using the definition (4.4) of two-particle states in terms of the creation operators $a_p^{\dagger\mathcal{M}}$'s:

$$|q, p\rangle_\theta^{\mathcal{M}} = a_p^{\mathcal{M}\dagger} a_q^{\mathcal{M}\dagger}|0\rangle = c_p^\dagger \exp\left(\frac{i}{2}p_\mu \theta^{\mu\nu}P_\nu\right)c_q^\dagger|0\rangle$$

$$= \mathrm{e}^{-\frac{i}{2}\vec{q} \wedge \vec{p}}a_q^\dagger \exp(-\frac{i}{2}q_\mu \theta^{\mu\nu}P_\nu)c_p^\dagger|0\rangle = \mathrm{e}^{-i\vec{q} \wedge \vec{p}}|p, q\rangle_\theta,$$

where we have used the relation introduced above and the fact that $c_p^\dagger$ and $c_q^\dagger$ commute. So these creation operators do implement the statistics we want.

The operators defined in (4.1), (4.2) are called in the literature [18, 19, 20] as *dressed operators*. They are obtained from the $\theta = 0$ ones by *dressing* them using the exponential term. Exploiting a peculiar property of the Moyal plane, which will be explained in the next section, we can obtain the Hermitian quantum field $\varphi_\theta^{\mathcal{M}}$ on the Moyal plane:

$$\varphi_\theta^{\mathcal{M}}(x) = \int \mathrm{d}\mu(p)\left[a_p^{\mathcal{M}}\mathrm{e}_{-p}(x) + a_p^{\mathcal{M}\dagger}\mathrm{e}_p(x)\right], \tag{4.6}$$

where $\mathrm{e}_p(x)$ denotes $\mathrm{e}^{ip \cdot x}$ as usual, through a similar dressing of the standard $\theta = 0$ scalar field:

$$\varphi_\theta^{\mathcal{M}} = \varphi_0 \mathrm{e}^{\frac{1}{2}\overleftarrow{\partial}_\mu \theta^{\mu\nu}P_\nu}. \tag{4.7}$$

---

[3]In the case under study, because of the twisted statistics, the creation operators, and likewise their adjoints, do not commute. The order in which they act on a state becomes then an issue. The choice made here is motivated by asking for consistency [7]. The scalar product we consider for the definition of the adjoint is the one associated with the untwisted creation and annihilation operators.

This formula is first deduced for in-, out- or free-fields. For example,

$$\varphi_\theta^{\mathcal{M},\text{in}} = \varphi_0^{\text{in}} e^{\frac{1}{2}\overleftarrow{\partial}_\mu \theta^{\mu\nu} P_\nu}.$$

But since the Heisenberg field becomes the 'in' field as $x_0 \to -\infty$,

$$\varphi_0(x) \to \varphi_0^{\text{in}} \qquad \text{as} \quad x_0 \to -\infty,$$

and P_μ is time-independent, we (at least heuristically) infer (4.7) for the fully interacting Heisenberg field.

Products of the field (4.6) have a further remarkable property which we have called *self-reproducing property*:

$$\left(\varphi_\theta^{\mathcal{M}} \star_{\mathcal{M}} \varphi_\theta^{\mathcal{M}}\right)(x) = \left[(\varphi_0 \cdot \varphi_0)(x)\right] e^{\frac{1}{2}\overleftarrow{\partial}_\mu \theta^{\mu\nu} P_\nu},$$

where the $\cdot$ represents the standard point-wise product. This property generalises to products of N fields

$$\underbrace{\varphi_\theta^{\mathcal{M}} \star_{\mathcal{M}} \varphi_\theta^{\mathcal{M}} \star_{\mathcal{M}} \cdots \star_{\mathcal{M}} \varphi_\theta^{\mathcal{M}}}_{N\text{-factors}} = \varphi_0^N e^{\frac{1}{2}\overleftarrow{\partial}_\mu \theta^{\mu\nu} P_\nu}, \tag{4.8}$$

where again φ_0^N indicates the N-th power with respect the commutative product m_0. This self-reproducing property plays a significant role in general theory. It is the basis for the proof of the absence of UV-IR mixing in Moyal field theories (with no gauge fields) [21, 22].

Now consider the Wick–Voros case. The twisted creation operators, which correctly create states from the vacuum transforming under the twisted coproduct, are [16]

$$a_p^{V\dagger} = c_p^\dagger e^{\frac{i}{2}(p_\mu \theta^{\mu\nu} P_\nu - i\theta p_\nu P_\nu)}, \tag{4.9}$$

where $p_\nu P_\nu$ uses the Euclidean scalar product. Its adjoint is

$$a_p^V = e^{-\frac{i}{2}(p_\mu \theta^{\mu\nu} P_\nu + i\theta p_\nu P_\nu)} c_p. \tag{4.10}$$

We prove elsewhere [23] that (4.9) and (4.10) are also dictated by the covariance of quantum fields.

It can be shown that, like in Moyal case, the states obtained by the action of $a_\theta^{V\dagger}$ reproduce the appropriate twisted statistics too.

Although we have obtained, like in Moyal, (4.9) and (4.10) by dressing the $\theta = 0$ operators, the quantum field φ_θ^V on Wick–Voros plane:

$$\varphi_\theta^V(x) = \int d\mu(p) \left[a_p^V e_{-p}(x) + a_p^{V\dagger} e_p(x)\right] \tag{4.11}$$

cannot be obtained from an overall dressing like in (4.7). This property fails due to the fact that is not possible to factorise the same overall exponential out of both (4.9) and (4.10), since it is not possible in (4.9), (4.10) to move the exponential from right (left) to left (right), that is:

$$a_p^{V\dagger} \neq \exp\left(-\frac{i}{2}(p_\mu \theta^{\mu\nu} P_\nu + i\theta p_\nu P_\nu)\right) c_p^\dagger,$$
$$a_p^V \neq c_p \exp\left(-\frac{i}{2}(p_\mu \theta^{\mu\nu} P_\nu + i\theta p_\nu P_\nu)\right). \tag{4.12}$$

This is because $c_p^\dagger$ and c_p do not commute with the exponentials in (4.9) and (4.10), in fact moving $c_p^\dagger$ (c_p) to the right (left) will bring a factor $\mathrm{e}^{-\frac{\theta}{2}p_\nu p_\nu}$:

$$a_p^{V\dagger} = \exp\left(\frac{i}{2}(p_\mu\theta^{\mu\nu}P_\nu - i\theta p_\nu P_\nu) - \frac{\theta}{2}p_\nu p_\nu\right)c_p^\dagger,$$

$$a_p^V = c_p\exp\left(-\frac{i}{2}(p_\mu\theta^{\mu\nu}P_\nu + i\theta p_\nu P_\nu) - \frac{\theta}{2}p_\nu p_\nu\right).$$

A consequence is that we have to twist the creation-annihilation parts $\varphi_0^{(\pm)I}$ ($I =$ in-, out- or free-) fields separately:

$$\varphi_\theta^{(+)V,I} = \int \mathrm{d}\mu(p)a^{V,I\dagger}\mathrm{e}_p = \varphi_0^{(+)I}e^{\frac{1}{2}(\overleftarrow{\partial}_\mu\theta^{\mu\nu}P_\nu - i\theta\overleftarrow{\partial}_\mu P_\mu)},$$

$$\varphi_\theta^{(-)V,I} = \int \mathrm{d}\mu(p)a^{V,I}\mathrm{e}_{-p} = e^{\frac{1}{2}(\overrightarrow{\partial}_\mu\theta^{\mu\nu}P_\nu + i\theta\overrightarrow{\partial}_\mu P_\mu)}\varphi_0^{(-)I},$$

$$\mathrm{e}_p(x) = \mathrm{e}^{ip\cdot x}, \qquad \mathrm{d}\mu(p) := \frac{\mathrm{d}^3 p}{2\sqrt{\vec{p}^2 + m^2}}, \qquad m = \text{mass of the field } \varphi_0^I,$$

where now we have added the superscript I to φ_0^I, $a_p^{V,I\dagger}$, and $a_p^{V,I}$.

Therefore to obtain the field (4.11) we have to twist creation and annihilation parts separately

$$\varphi_\theta^{V,I} = \varphi_\theta^{(+)V,I} + \varphi_\theta^{(-)V,I}. \tag{4.13}$$

A further point relates to the self-reproducing property of these Wick–Voros fields. The quantum fields $\varphi_\theta^{(\pm)IV}$ are self-reproductive, but in different ways. Thus

$$\underbrace{\varphi_\theta^{(+)V,I} \star_V \varphi_\theta^{(+)V,I} \star_V \cdots \star_V \varphi_\theta^{(+)V,I}}_{M\text{-factors}} = \left(\varphi_0^{(+)I}\right)^M e^{\frac{1}{2}(\overleftarrow{\partial}_\mu)\theta^{\mu\nu}P_\nu - i\theta\overleftarrow{\partial}_\mu P_\mu},$$

$$\underbrace{\varphi_\theta^{(-)V,I} \star_V \varphi_\theta^{(-)V,I} \star_V \cdots \star_V \varphi_\theta^{(-)V,I}}_{M'\text{-factors}} = e^{\frac{1}{2}(\overrightarrow{\partial}_\mu)\theta^{\mu\nu}P_\nu + i\theta\overrightarrow{\partial}_\mu P_\mu}\left(\varphi_0^{(-)I}\right)^{M'},$$

where, as in (4.8), $\left(\varphi_0^{(\pm)I}\right)^N$ is the N-th power of $\varphi_0^{(\pm)I}$ with respect to the commutative product m_0. Given (4.13), it follows that the full field, φ_θ^V, does not have the self-reproducing property.

5 Voros versus Moyal: a comparison

It is now time to compare the two theories we have previously introduced. We will follow the treatment in [17] and prove them to be inequivalent. First we want to approach this question of equivalence from a heuristic point of view. We will conclude this section proving that no similarity transformation can relate the two theories, showing their inequivalence with respect to isospectral transformations.

The first big difference among QFT's on Moyal and Wick–Voros planes has already appeared above. Although we have not stressed it, (4.1) and (4.2) could have been changed to

$$a_p^{\mathcal{M}} = \exp\left(-\frac{i}{2}p_\mu\theta^{\mu\nu}P_\nu\right)c_p, \tag{5.1}$$

$$a_p^{\mathcal{M}\dagger} = \exp\left(\frac{i}{2}p_\mu\theta^{\mu\nu}P_\nu\right)c_p^\dagger. \tag{5.2}$$

But in fact (4.1) equals (5.1) and (4.2) equals (5.2) because $\theta^{\mu\nu} = -\theta^{\nu\mu}$ [15, 24]. In (4.12) we have instead seen that this is not the case for the Wick–Voros plane. This observation is important since it ensures that the Moyal field (4.6), which we can obtain from the $\theta = 0$ field by twisting it, is Hermitian. Had we constructed the Voros field in a similar way, we would have ended up with a non-Hermitian operator.

Equation (4.12) is also the reason for the absence of the self-reproducing property on the Wick–Voros plane that by itself causes differences at the level of physics. (For example the arguments for the absence of UV/IR mixing on the Moyal plane would fail here.)

But that is not all. The states in the Wick–Voros case are not normalised in the same way as in the Moyal case. For instance

$$\langle k_1, k_2 | p_1, p_2 \rangle \equiv \langle 0 | a^{V,I}_{k_1} a^{V,I}_{k_2} a^{V,I\dagger}_{p_2} a^{V,I\dagger}_{p_1} | 0 \rangle = \mathrm{e}^{\theta k_1 \cdot k_2} 4 \sqrt{(\vec{k}_1^2 + m^2)(\vec{k}_2^2 + m^2)}$$
$$\times \left[\delta^3(k_1 - p_1)\delta^3(k_2 - p_2) + \mathrm{e}^{\frac{i}{2}k_{1\mu}\theta^{\mu\nu}k_{2\nu}} \delta^3(k_1 - p_2)\delta^3(k_2 - p_1) \right], \tag{5.3}$$
$$\mathrm{I} = \mathrm{in, \ out}, \qquad |0\rangle_{\mathrm{in}} = |0\rangle_{\mathrm{out}}, \qquad m = \text{mass of the field } \varphi_0^I.$$

For scattering theory, normalisation is important. It depends on the scalar product we are using. If we normalise the states as in the Moyal case, since the normalisation constant in (5.3) is momentum dependent, the normalised states no longer transform with the Wick–Voros coproduct. The factor (5.3) has been computed using the standard scalar product in the Fock space. We can try changing it [16] so that the states become correctly normalised. But then the representation $(a, \Lambda) \to U(a, \Lambda)$ ceases to be unitary. We can try to seek for another one, modifying $U(a, \Lambda)$ using a non trivial operator $\mathcal{O}$. We could not find any such $\mathcal{O}$ which would preserve the way the unitary representation has to act on single particle states. It then appears that the Wick–Voros plane is not suitable for quantum physics.

We now show that there is no similarity transformation taking $a^{\mathcal{M},I}_p$, $a^{\mathcal{M},I\dagger}_p$ into $a^{V,I}_p$, $a^{V,I\dagger}_p$. One way to quickly see this is to examine the operators without the Moyal part of the twist. So we consider c^I_p, $c^{I\dagger}_p$ and

$$a^{V,I'}_p = \mathrm{e}^{\frac{1}{2}\theta p_\nu P_\nu} c^I_p, \tag{5.4}$$
$$a^{V,I'\dagger}_p = c^{I\dagger}_p \mathrm{e}^{\frac{1}{2}\theta p_\nu P_\nu}. \tag{5.5}$$

Now

$$[c^I_p, c^{I\dagger}_k] = 2|p_0|\delta^3(p - k)\mathbb{1},$$
$$p_0 = \sqrt{\vec{p}^2 + m^2}, \qquad m = \text{mass of the field } \varphi_0^I.$$

Had there existed an invertible operator W such that

$$W c^I_p W^{-1} = a^{V,I'}_p, \qquad W c^{I\dagger}_p W^{-1} = a^{V,I'\dagger}_p,$$

then we would have

$$[a^{V,I'}_p, a^{V,I'\dagger}_k] = 2|p_0|\delta^3(p - k)\mathbb{1}. \tag{5.6}$$

But a direct calculation of the l.h.s. using (5.4), (5.5) shows that (5.6) is not true.

However there exists an invertible operator S which transforms $a^{\mathcal{M},I\dagger}_p$ to $a^{V,I\dagger}_p$ and is given by:

$$S = \mathrm{e}^{\frac{\theta}{4}(P_\mu P_\mu + K)}, \qquad K = -\int \mathrm{d}\mu(k) k_\mu k_\mu c^{I\dagger}_k c^I_k \tag{5.7}$$

and a simple computation now shows that

$$Sa_p^{\mathcal{M},\mathrm{I}\dagger}S^{-1} = a_p^{V,\mathrm{I}\dagger}.$$

where, as usual, I on $c_k^{\mathrm{I}\dagger}$, c_k^{I} denotes in-, out- or free- while in $P_\mu P_\mu$ and $k_\mu k_\mu$, we use the Euclidean scalar product.

But

$$Sa_p^{\mathcal{M},\mathrm{I}}S^{-1} = \mathrm{e}^{-\frac{i}{2}(p_\mu\theta^{\mu\nu}P_\nu - i\theta p_\nu p_\nu)}c_p^{\mathrm{I}} = \tilde{a}_p^{V,\mathrm{I}} \neq a_p^{V,\mathrm{I}}.$$

Let us pursue the properties of this operator further.

The operator S leaves the vacuum invariant and shows that certain correlators in the Moyal and Wick–Voros cases are equal. From the explicit expression (5.7) it follows also that the map induced by the operator S is isospectral, but not unitary in the Fock space scalar product. It is possible to define a new scalar product which makes S unitary [16]. But the previously defined $U(a,\Lambda)$ would not be unitary in this scalar product as we discussed above.

Now consider the twisted fields

$$\varphi_\theta^{\mathcal{M},\mathrm{I}} = \int \mathrm{d}\mu(p)\big[a_p^{\mathcal{M},\mathrm{I}}\mathrm{e}_{-p} + a_p^{\mathcal{M},\mathrm{I}\dagger}\mathrm{e}_p\big],$$

$$\tilde{\varphi}_\theta^{V,\mathrm{I}} = \int \mathrm{d}\mu(p)\big[\tilde{a}_p^{V,\mathrm{I}}\mathrm{e}_{-p} + a_p^{V,\mathrm{I}\dagger}\mathrm{e}_p\big],$$

where $\mathrm{e}_p(x)$ denotes $\mathrm{e}^{ip\cdot x}$ as before. Then of course,

$$S: \ \varphi_\theta^{\mathcal{M},\mathrm{I}} \to S \triangleright \varphi_\theta^{\mathcal{M},\mathrm{I}} := \int \mathrm{d}\mu(p)S\big[a_p^{\mathcal{M},\mathrm{I}}\mathrm{e}_{-p} + a_p^{\mathcal{M},\mathrm{I}\dagger}\mathrm{e}_p\big]S^{-1} = \tilde{\varphi}_\theta^{V,\mathrm{I}}. \tag{5.8}$$

Also

$$S|0\rangle = S^{-1}|0\rangle = 0. \tag{5.9}$$

From (5.8) and (5.9) we obtain trivially the equality of the n-points correlation functions:

$$\langle\varphi_\theta^{\mathcal{M},\mathrm{I}}(x_1)\varphi_\theta^{\mathcal{M},\mathrm{I}}(x_2)\cdots\varphi_\theta^{\mathcal{M},\mathrm{I}}(x_N)\rangle_0 = \langle\tilde{\varphi}_\theta^{V,\mathrm{I}}(x_1)\tilde{\varphi}_\theta^{V,\mathrm{I}}(x_2)\cdots\tilde{\varphi}_\theta^{V,\mathrm{I}}(x_N)\rangle_0.$$

Consider simple interaction densities such as

$$\mathscr{H}_\mathrm{I}^{\mathcal{M}} = \underbrace{\varphi_\theta^{\mathcal{M},\mathrm{I}} \star_{\mathcal{M}} \varphi_\theta^{\mathcal{M},\mathrm{I}} \star_{\mathcal{M}} \cdots \star_{\mathcal{M}} \varphi_\theta^{\mathcal{M},\mathrm{I}}}_{N\text{-factors}} \quad \text{and} \quad \mathscr{H}_\mathrm{I}^{V} = \underbrace{\tilde{\varphi}_\theta^{V,\mathrm{I}} \star_{V} \tilde{\varphi}_\theta^{V,\mathrm{I}} \star_{V} \cdots \star_{V} \tilde{\varphi}_\theta^{V,\mathrm{I}}}_{N\text{-factors}}$$

in either field. Since S only acts on the operator parts of the fields, the similarity transformation in (5.8) will not map $\mathscr{H}_\mathrm{I}^{\mathcal{M}}$ to $\mathscr{H}_\mathrm{I}^{V}$:

$$S \triangleright \mathscr{H}_\mathrm{I}^{\mathcal{M}} \neq \mathscr{H}_\mathrm{I}^{V}.$$

Hence

$$\langle\varphi_\theta^{\mathcal{M},\mathrm{I}}(x_1)\cdots\varphi_\theta^{\mathcal{M},\mathrm{I}}(x_j)\mathscr{H}_\mathrm{I}^{\mathcal{M}}(x_{j+1})\varphi_\theta^{\mathcal{M},\mathrm{I}}(x_{j+2})\cdots\varphi_\theta^{\mathcal{M},\mathrm{I}}(x_N)\rangle_0$$
$$\neq \langle\tilde{\varphi}_\theta^{V,\mathrm{I}}(x_1)\cdots\tilde{\varphi}_\theta^{V,\mathrm{I}}(x_j)\mathscr{H}_\mathrm{I}^{V}(x_{j+1})\tilde{\varphi}_\theta^{V,\mathrm{I}}(x_{j+2})\cdots\tilde{\varphi}_\theta^{V,\mathrm{I}}(x_N)\rangle_0.$$

So we can immediately conclude that also in this case the two theories are different.

There is no such S for mapping $\varphi_\theta^{\mathcal{M},\mathrm{I}}$ to $\varphi_\theta^{V,\mathrm{I}}$, so that the correlators are not equal even at the tree level.

6   Further formal developments

In the presentation we have given so far, the Hopf algebra deformation has been introduced to compensate for the spacetime noncommutativity (1.1) and restore the Poincaré invariance of the theory. The algebra of functions on spacetime and the Poincaré group are related by a duality in a very precise manner. The consequence of that is that once one of the two is deformed, the duality relation imposes a similar deformation on the other. A deformation of the coproduct of the Poincaré group thus induces a noncommutative spacetime [25]. Thus while customarily, we deduce the Hopf algebra deformations from spacetime noncommutativity, we can also deduce the latter from the former.

Also, so far we have not discussed gauge theory to any extent. In the approach to gauge theories followed in [26, 27], a unique feature seems to arise due to the deformation needed in the presence of gauge fields: the coproduct deformation is not coassociative. Because of the dual relation cited above, the product between functions on spacetime induced by such a noncoassociative coproduct is also nonassociative [28].

Both of these more formal features deserve to be discussed in more detail.

6.1   Spacetime from symmetry

The starting point to unveil the duality that ties the Hopf algebra deformation with the deformation on the spacetime algebra, is to recall a well-known result. The commutative algebra of functions on spacetime, what we have called $\mathcal{A}_0 \equiv (\mathscr{F}(\mathbb{R}^4), m_0)$, can be obtained as a coset of the algebra of functions on the Poincaré group with respect to the right action of the proper ortochronous Lorentz group $\mathcal{L}_+^\uparrow$. This result exploits the fact that the Poincaré group is the semi-direct product of translations and the Lorentz group, so that $\mathbb{R}^4 \cong \mathscr{P}/\mathcal{L}_+^\uparrow$. It is crucial to stress that the reason why such a coset description of $\mathbb{R}^4$ gives the algebraic structure of $\mathcal{A}_0$ is because the product of two right-invariant functions under the action of $\mathcal{L}_+^\uparrow$ on the Poincaré group it is still right invariant.

In order to generalise such a construction to the noncommutative case, we should also mention that it is well known in Hopf algebra theory that the product structure on functions on any Lie group $\mathscr{F}(\mathscr{G})$ and the group algebra $\mathbb{C}\mathscr{G}$ are dual to each other. Such a duality is a remarkably powerful tool. Given the Hopf algebra structure on the group algebra $\mathbb{C}\mathscr{G}$, that is given the multiplication map m and the coproduct Δ, and the duality map:

$$\forall f \in \mathscr{F}(\mathscr{G}), \quad \forall g \in \mathbb{C}\mathscr{G} \qquad \langle f, g \rangle = f(g) \in \mathbb{C} \tag{6.1}$$

we can deduce a multiplication map m^* and a coproduct Δ^* on $\mathscr{F}(\mathscr{G})$ turning $\mathscr{F}(\mathscr{G})$ also into a Hopf algebra. The structures on $\mathscr{F}(\mathscr{G})$, (m^*, Δ^*), are uniquely deduced in the following way:

$$\forall f_1, f_2 \in \mathscr{F}(\mathscr{G}), \ \forall g \in \mathbb{C}\mathscr{G}, \qquad (f_1 \cdot f_2)(g) \equiv \langle m^*(f_1 \otimes f_2), g \rangle := (f_1 \otimes f_2)(\Delta(g)), \tag{6.2}$$
$$\forall f \in \mathscr{F}(\mathscr{G}), \ \forall g_1, g_2 \in \mathbb{C}\mathscr{G}, \qquad \Delta(f)(g_1 \otimes g_2) \equiv \langle \Delta^*(f), g_1 \otimes g_2 \rangle := f(g_1 \cdot g_2).$$

In this approach, a co-commutative Δ on $\mathbb{C}\mathscr{G}$, like the choice (2.4), induces a commutative multiplication map on functions. It is then natural to expect that if we deform the costructure of $\mathbb{C}\mathscr{P}$, like in (2.5), then on the dual, that is on the functions on Poincaré group, we will obtain a noncommutative multiplication map.

We will work with $H_\theta^{\mathcal{M}}\mathscr{P}$. Its coproduct is obtained from the standard coproduct on $\mathbb{C}\mathscr{P}$ using the Moyal twist introduced in (3.6). In order to get an algebra of functions on spacetime from $\mathscr{F}(\mathscr{P})$, as explained above, we should make sure that the coset operation is compatible with the noncommutative product induced by (6.2) when $\Delta \equiv \Delta_\theta^{\mathcal{M}}$. Such a requirement will fix how the duality pairing (6.1) gets lifted to the tensor product space. Once this lift is fixed,

there is no more freedom allowed and we can proceed to compute the multiplication map m_θ^* on the algebra $\mathscr{F}(\mathscr{P})$ using (6.2). In [25] we have found such a lift and we have explicitly shown that such a product m_θ^* coincides exactly with the standard Moyal product on $\mathscr{F}(\mathbb{R}^4)$ $m_\theta^{\mathcal{M}}$ as in (3.4).

6.2 Nonassociative deformations

Gauge theories in noncommutative QFT's have been a long standing problem. The main complication is the non-closure of the commutator of covariant derivatives if connections are non-commutative. Thus:

$$
\begin{aligned}
[\mathbf{A}_\mu, \mathbf{A}_\nu](x) &= [A_\mu^a \lambda^a, A_\nu^b \lambda^b](x) \\
&= \left(A_\mu^a \star A_\nu^b - A_\nu^b \star A_\mu^a \right)(x) \lambda^a \lambda^b + \left(A_\mu^a \star A_\nu^b \right)(x) f_c^{ab} \lambda^c, \qquad \lambda^i \in \mathfrak{g},
\end{aligned}
$$

where $\mathfrak{g}$ is the Lie algebra. Now $\lambda^a \lambda^b \notin \mathfrak{g}$, unless the Lie group $\mathscr{G}$ is $U(N)$ where N is the dimension of the particular representation under consideration. The Lie group in this way becomes the whole unitary group if λ^a's describe an irreducible representation. Its dimension is also dependent on the representation of λ^a. One way out is to assume standard point-wise multiplication among gauge fields so that the extra term, proportional to $[A_\mu^a, A_\nu^b]_\star(x)$, vanishes as it usually does. We will follow this approach. More formally we will consider connections as $\mathscr{G}$-valued functions on the commutative algebra $\mathcal{A}_0 \equiv (\mathscr{F}(\mathbb{R}^4), m_0)$, where $\mathscr{G}$ is the gauge group. The fields A_μ^θ are then not twisted: $A_\mu^\theta = A_\mu^0$. Such a formulation, where matter fields are twisted, that is regarded as elements of $\mathcal{A}_\theta \equiv (\mathscr{F}(\mathbb{R}^4), m_\theta)$, while gauge fields are treated as standard commutative functions, can be shown to be internally consistent. The basic reason is that $\mathcal{A}_\theta$ is an $\mathcal{A}_0$ module. We refer to [26, 27] for more details.

In this approach, the deformation of the action of the Poincaré–Hopf algebra on tensor product spaces shows up only through matter fields. In the particular case in which we choose the Moyal plane $\mathcal{A}_\theta \equiv \mathcal{A}_\theta^{\mathcal{M}}$ for the matter part, the deformed coproduct $\overline{\Delta}_\theta$ which acts both on $\varphi_\theta^{\mathcal{M}}$ and $A_\theta^\mu = A_0^\mu$ has to fulfill

$$
\begin{aligned}
\overline{\Delta}_\theta|_{\text{Gauge fields}} &= \Delta_0, \\
\overline{\Delta}_\theta|_{\text{Matter fields}} &= \Delta_\theta^{\mathcal{M}} = \left(F_\theta^{\mathcal{M}} \right)^{-1} \Delta_0 F_\theta^{\mathcal{M}}.
\end{aligned}
$$

In order to write an expression for $\overline{\Delta}_\theta$ which would take care of both gauge and matter sections, we need to enlarge the group algebra $\mathbb{C}\mathscr{P}$. Specifically we should introduce a central element u which will act effectively as a grading operator for the quantum fields. We call the extended group algebra $\overline{\mathbb{C}\mathscr{P}}$.

Let us denote by $\chi_0^{g,m}$ a generic untwisted gauge and matter field. The central element u acts on them by conjugation, we will denote such an action as usual as Ad:

$$
\mathrm{Ad}(u) \chi_0^{g,m} := u \chi_0^{g,m} u^{-1}.
$$

We define the action of u so that gauge fields are even whereas matter fields are odd:

$$
\mathrm{Ad}(u) \chi_0^g = \chi_0^g, \qquad \mathrm{Ad}(u) \chi_0^m = -\chi_0^m.
$$

It then follows that the operator

$$
\delta_{\mathrm{Ad}\, u, -\mathbb{1}} \equiv \frac{1}{2} [\mathbb{1} - \mathrm{Ad}(u)] \tag{6.3}
$$

acts as identity on matter fields χ_0^m and as 0 on gauge ones χ_0^g.

We have now introduced enough formalism to present the definition of the extended coproduct $\overline{\Delta}_\theta$:

$$\overline{\Delta}_\theta := \mathfrak{F}_\theta^{-1} \Delta_0 \mathfrak{F}_\theta, \tag{6.4}$$

where now the twist operator $\mathfrak{F}_\theta$ is given by

$$\mathfrak{F}_\theta = \mathrm{e}^{-\frac{i}{2} P_\mu \theta^{\mu\nu} \otimes P_\nu (\delta_{\mathrm{Ad}\, u}, -\mathbb{1} \otimes \mathbb{1})}.$$

Using (6.3), $\mathfrak{F}_\theta$ can be checked to reduce to the identity map on the gauge sector and the standard Moyal twist $F_\theta^{\mathcal{M}}$ (3.6) on matter fields.

We want to study the coproduct deformation introduced in (6.4) further. Specifically we want to study its so-called coassociativity. A coproduct Δ is said to be coassociative if the following equation is fulfilled:

$$(\Delta \otimes \mathbb{1})\Delta(g) = (\mathbb{1} \otimes \Delta)\Delta(g), \qquad \forall\, g \in \mathbb{C}\mathscr{P}. \tag{6.5}$$

Both l.h.s. and r.h.s. define an action of $\mathbb{C}\mathscr{P}$ on a three particles state. If the coproduct is coassociative there is no ambiguity in the definition of the action of $\mathbb{C}\mathscr{P}$ on three, and actually on any multiparticle state. Coassociativity of Δ is assumed when we deal with Hopf algebras. The lack of it will change a Hopf algebra to what is called a quasi-Hopf algebra (see for instance [10]).

In order to show that (6.4) is not coassociative, we can compute the action both of l.h.s. and r.h.s. of (6.5), with $\Delta \equiv \overline{\Delta}_\theta$, on vectors $e_p \otimes e_q \otimes e_k \in V_{\mathrm{Gauge}} \otimes V_{\mathrm{Matter}} \otimes V_{\mathrm{Matter}}$. V_{Gauge} and V_{Matter} denote the even and odd vector spaces under u and e_r $(r = p, q, k)$ denote plane wave vectors: $e_r(x) := \mathrm{e}^{ir \cdot x}$. In [28] it has been shown that $(\overline{\Delta}_\theta \otimes \mathbb{1})\overline{\Delta}_\theta$ and $(\mathbb{1} \otimes \overline{\Delta}_\theta)\overline{\Delta}_\theta$ transform $e_p \otimes e_q \otimes e_k$ in different ways. Thus $\overline{\Delta}_\theta$ is not coassociative and $\overline{H_\theta \mathscr{P}}$, that is the deformation of the Hopf–Poincaré algebra when gauge fields also are included in the picture, is a quasi-Hopf algebra.

Given the deformation $\overline{H_\theta \mathscr{P}}$, the deformation on the algebra of functions $\mathscr{F}(\mathbb{R}^4)$ can be obtained using duality as explained previously. It is a standard result that the multiplication map m^* induced on the dual Hopf algebra is associative if and only if the starting Δ is coassociative. In $\overline{H_\theta \mathscr{P}}$, the coproduct we need to consider is $\overline{\Delta}_\theta$. The multiplication map on functions on spacetime $\overline{\star}$ induced by (6.2) is hence nonassociative:

$$f_1, f_2, f_3 \in \mathscr{F}(\mathbb{R}^4), \qquad (f_1 \overline{\star} f_2)\overline{\star} f_3 \neq f_1 \overline{\star}(f_2 \overline{\star} f_3).$$

This is a striking result which deserves more study. In particular one can try to understand how to formulate quantum mechanics on such nonassociative spacetimes.

7 Experimental bounds on θ

In the following we will present some bounds for the noncommutativity parameter θ provided by the most recent experiments. Most of them deal with QFT on the Moyal plane.

7.1 Modifications of the CMB spectrum

The Cosmic Microwave Background (CMB) radiation gives us a picture of the universe when it was only 400,000 years old. The smallness of the anisotropies detected by COBE in 1992 have suggested that what we see today is how the universe appeared at the end of an era of exponential expansion called inflation. The inflation era stretched a region of Planck size into cosmological scales. We then expect that the CMB radiation would show some signatures of physics at Planck scale too. That is the reason why descriptions of CMB radiation in the noncommutative

framework have been addressed in many places [29, 30, 31, 32, 33, 34, 35, 36, 37, 38]. We will report the results of [39, 40] which use the approach to QFT on noncommutative spaces introduced above. We will only report the most important formulas and results, referring to the original papers for details. The $\theta = 0$ calculation can be found in [41, 42, 43].

The observational data used to constrain the noncommutative parameter θ were obtained from WMAP5 [44, 45, 46], ACBAR [47, 48, 49] and CBI [50, 51, 52, 53, 54]. All these experiments have measured the anisotropy in the temperature of the CMB.

The temperature fluctuations can be expanded in spherical harmonics:

$$\frac{\Delta T(\hat{n})}{T} = \sum_{lm} a_{lm} Y_{lm}(\hat{n}),$$

where $\hat{n}$ is the direction of the incoming photons.

The coefficients of spherical harmonics, a_{lm}, contain all the information encoded in the temperature fluctuations. They can be connected to the primordial scalar metric perturbation caused by the quantum fluctuations of the inflaton field:

$$a_{lm}^{0,\theta} = 4\pi(-i)^l \int \frac{\mathrm{d}^3 k}{(2\pi)^3} \Delta_l(k) \varphi_{0,\theta}(\vec{k}, \eta) Y_{lm}^*(\hat{k}),$$

where $\Delta_l(k)$ are called *transfer functions*, $\eta = \frac{t}{a(t)}$ is the cosmological time and $\varphi_{0,\theta}(\vec{k}, \eta)$ is the inflaton field in momentum space which for $\theta \neq 0$ is taken to be given by the Moyal quantum field (4.6). We can now introduce the two-point temperature correlation function, which can also be expanded in spherical harmonics:

$$\left\langle \frac{\Delta T(\hat{n})}{T} \frac{\Delta T(\hat{n}')}{T} \right\rangle = \sum_{lm, l'm'} \langle a_{lm} a_{l'm'}^* \rangle Y_{lm}^*(\hat{n}) Y_{l'm'}(\hat{n}'),$$

where

$$\langle a_{lm} a_{l'm'}^* \rangle_{0,\theta} = 16\pi^2 (-i)^{l-l'} \int \frac{\mathrm{d}^3 k}{(2\pi)^3} \Delta_l(k) \Delta_{l'}(k) P_{\varphi_{0,\theta}}(\vec{k}) Y_{lm}^*(\hat{k}) Y_{l'm'}(\hat{k}). \tag{7.1}$$

The function $P_{\varphi_{0,\theta}}(\vec{k})$ is called *power spectrum* and is defined in terms of the real part of the two-point correlation function in momentum space:

$$\langle \varphi_{0,\theta}(\vec{k}, \eta) \varphi_{0,\theta}^\dagger(\vec{k}', \eta) \rangle = (2\pi)^3 P_{\varphi_{0,\theta}}(\vec{k}) \delta^3(\vec{k} - \vec{k}').$$

It is $P_{\varphi_{0,\theta}}(\vec{k})$ which contains the signature of noncommutativity. The expression for the power spectrum when a mode k crosses the horizon, that is when $a(\eta)H = k$ say for $\eta = \eta_0$, in the commutative limit and in the $\theta \neq 0$ cases, are respectively:

$$P_{\varphi_0}(\vec{k}) = \frac{16\pi G}{9\epsilon} \frac{H^2}{2k^3} \bigg|_{a(\eta_0)H=k}, \tag{7.2}$$

$$P_{\varphi_\theta}(\vec{k}) = P_{\varphi_0}(\vec{k}) \cosh\left(H\vec{\theta}^0 \cdot \vec{k}\right). \tag{7.3}$$

These formulas above are obtained assuming the Hubble parameter H to be constant during inflation, ϵ is the slow-roll parameter in the single field inflation model [41] and $\vec{\theta}^0 := (\theta^{01}, \theta^{02}, \theta^{03})$.

Substituting (7.2) and (7.3) in (7.1) we get for the two cases:

$$\langle a_{lm} a_{l'm'}^* \rangle_0 = \frac{2}{\pi} \int \mathrm{d}k \, k^2 \, (\Delta_l(k))^2 P_{\varphi_0}(k) \delta_{ll'} \delta_{mm'} \equiv C_l \delta_{ll'} \delta_{mm'} \tag{7.4}$$

$$\langle a_{lm} a^*_{l'm'} \rangle_\theta = \frac{2}{\pi} \int \mathrm{d}k \sum_{l''=0,\, l'':\mathrm{even}}^{\infty} (i)^{l-l'} (-1)^m (2l''+1) k^2 \Delta_l(k) \Delta_{l'}(k) P_{\varphi_0}(k) i_{l''}(\theta k H)$$

$$\times \sqrt{(2l+1)(2l''+1)} \begin{pmatrix} l & l' & l'' \\ 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} l & l' & l'' \\ -m & m' & 0 \end{pmatrix}, \tag{7.5}$$

where $i_l(z)$ is the modified spherical Bessel function, while the Wigner's 3-j symbols come from integrals of spherical harmonics:

$$\int \mathrm{d}\Omega_k Y_{l,-m}(\hat{k}) Y_{l',m'}(\hat{k}) Y_{l'',0}(\hat{k}) = \sqrt{\frac{(2l+1)(2l'+1)(2l''+1)}{4\pi}} \begin{pmatrix} l & l' & l'' \\ 0 & 0 & 0 \end{pmatrix} \begin{pmatrix} l & l' & l'' \\ -m & m' & 0 \end{pmatrix}.$$

From (7.4) we get the definition of C_l, that is the power spectrum for multipole moment l. The data sets from WMAP5, ACBAR and CBI are only available for such diagonal terms. We can then consider (7.5) for $l = l'$ and average over m to get a much simpler expression:

$$C_l^\theta \equiv \frac{1}{2l+1} \sum_m \langle a_{lm} a^*_{lm} \rangle_\theta = \int \mathrm{d}k \; k^2 \; P_{\varphi_\theta}(k) |\Delta_l(k, \eta = \eta_0)|^2 i_0(\theta k H). \tag{7.6}$$

Here the coefficients $C_l^0 \equiv C_l$ in the $\theta = 0$ are given by (7.4).

A comparison between (7.4) and (7.6) with the available data shows [40] that it is not possible to constrain θ using WMAP data. This is due to the fact that the last data point in the WMAP observations is at a relatively small value for angular momentum l ($l = 839$) whereas the signature of noncommutativity appears at very high values of l. Using data from ACBAR and CB instead, which go up to $l = 2985$ and $l = 3500$ respectively, we can get constraints on θ. The restriction we found on $H\theta$ is

$$H\theta < 0.01 \text{ Mpc}. \tag{7.7}$$

Data from ACBAR+WMAP3, give an upper limit on the Hubble parameter:

$$H < 1.704 \times 10^{-5} M_p, \tag{7.8}$$

where M_p is the Planck mass. We are interested in a value for θ at the end of inflation. The scale factor then, assuming a reheating temperature of the universe close to the GUT energy (10^{16} GeV), is $a \simeq 10^{-29}$ [41]. Using both (7.7) and (7.8) we finally get a bound for θ:

$$\sqrt{\theta} < \left(1.84 a \times 10^{-9}\right)^{1/2} = 1.36 \times 10^{-19} \text{ m},$$

which corresponds to a lower bound for the energy scale of 10 TeV.

7.2   Pauli-forbidden transitions

There have been suggestions [24] that the Pauli principle will be modified on non-commutative spacetimes. In [55], the authors computed the statistical potential V_{STAT} among two twisted two-particle fermion states. V_{STAT} does not show an infinitely repulsive core, as it would be on commutative spacetimes. In [56] a concrete calculation of Pauli-forbidden transition has been carried out on a non-commutative spacetime. It leads to the bound $\gtrsim 10^{24}$ TeV for the energy scale of noncommutativity when combined with limits on Pauli-forbidden transitions from [57, 58, 59, 60, 61]. This is a strong bound suggesting an energy scale beyond the Planck scale.

The calculation is carried out using a twist deformation which is neither Moyal nor Wick–Voros. Specifically the twist has the form:

$$\mathcal{F}'_{\theta\hat{n}} := \mathrm{e}^{-\frac{i\theta}{2}(P_0 \otimes \hat{n} \cdot \vec{J} - \hat{n} \cdot \vec{J} \otimes P_0)}, \tag{7.9}$$

where P_0 and $\vec{J}$ are respectively the time translation and rotations generators and $\hat{n}$ is a fixed unit vector. The twist (7.9) leads to a different kind of noncommutativity with respect to (1.1). Acting with the noncommutative product $m'_\theta := m_0 \circ \mathcal{F}'_{\theta\hat{n}}$ on coordinates functions we get

$$[\hat{x}_0, \hat{x}_j] = i\theta\epsilon_{ijk}n_i\hat{x}_k.$$

It can be shown that the twist (7.9) still defines a consistent Poincaré–Hopf algebra deformation. It is then possible to proceed to compute the twisted ground two-electron state of a Be atom:

$$|1,1\rangle_{\theta\hat{n}} = \frac{\mathbb{1} - \tau_{\theta\hat{n}}}{\sqrt{2}}|1,+1;1,-1\rangle_{\hat{n}},$$

where $\tau_{\theta\hat{n}} = \left(\mathcal{F}'_{\theta\hat{n}}\right)^{-1}\tau_0\mathcal{F}_{\theta\hat{n}}$ is the new twisted flip operator (2.6) and the label $\hat{n}$ indicates that the states are $\vec{J}\cdot\hat{n}$ eigenstates with eigenvalue given by the second state label:

$$\vec{J}\cdot\hat{n}|\nu,\alpha\rangle_{\hat{n}} = \frac{\vec{\sigma}\cdot\hat{n}}{2}|\nu,\alpha\rangle_{\hat{n}} = \frac{\alpha}{2}|\nu,\alpha\rangle_{\hat{n}}, \qquad \alpha = \pm 1.$$

The first state label, that is ν in the above formula, indicates principal quantum number and hence the energy eigenvalue:

$$P_0|\nu,\alpha\rangle_{\hat{n}} = E_\nu|\nu,\alpha\rangle_{\hat{n}}.$$

Likewise we can compute the two-electron excited state

$$|2,+1;3,+1\rangle_{\theta\hat{n}} = \frac{\mathbb{1} - \tau_{\theta\hat{n}}}{\sqrt{2}}|2,+1;3,+1\rangle_{\hat{n}}. \tag{7.10}$$

We consider the case where two of the four electrons in Be are initially in the ground state and the remaining two in the state (7.10). Then in the standard $\theta = 0$ case, any transition from the excited state (7.10) to the ground state vanishes by Pauli principle as the ground state is fully occupied. Once the explicit expressions for the two states are obtained it is possible to compute the transition rate in the $\theta \neq 0$ case. In the noncommuativity case, the twisted statistics introduces a $\theta\hat{n}$ dependence in energy eigenstates. If we take into account the rotation around its axis and revolution around the sun, the Earth frame is a non-inertial one. This reflects in the fact that in this frame the angular momentum generators rotate. Effectively, such a rotation can be seen on the axis identified by $\hat{n}$:

$$\hat{n}^i \to \hat{m}^i := \hat{n}^j R(t)^i_j, \qquad R(t) \in SO(3). \tag{7.11}$$

Hence the twisted flip operator goes into $\tau_{\theta\hat{m}}$. Such a change, $\tau_{\theta\hat{n}} \to \tau_{\theta\hat{m}}$ induces (twisted) bosonic components in multi-fermion (in the case of study electrons) state vectors leading to non-Pauli effects.

The time scale of the effect induced by the twisted flip operator in energy eigenstates is expected to be very large, of the order of the inverse of the Planck length. On the other side the effect of Earth rotation, as in (7.11), are at the most of the order of 1 year. A suitable approach to treat corrections due by such a short-scale effect is the *sudden approximation*, in the case under study is the rotation $R(t)$ of $\hat{n}$ which is considered as sudden effect. As $\hat{n}$ rotates, $\tau_{\theta\hat{n}}$ goes into $\tau_{\theta\hat{m}}$ but the states have "no time" to adjust, they in fact do not change in the sudden approximation. The states are then no longer eigenstates of the twisted flip operator $\tau_{\theta\hat{m}}$, this is the cause of the appearance of non-Pauli effects. The details of the calculation can be found in [56]. Comparison between the nonvanishing transition rate in the $\theta \neq 0$ case and the bounds on Pauli-forbidden transitions coming from nuclear physics [57, 58, 59, 60, 61] leads to the bound for the energy scale of the noncommutativity parameter $\gtrsim 10^{24}$ TeV given above.

7.3   Particle physics phenomenology

The noncommutativity parameter θ can also be constrained using particle physics experiments. Non-commutative spacetimes lead to CPT violation [62]. One of the strongest experimental supports to CPT symmetry comes from the mass difference of K^0 and $\overline{K}^0$ which is predicted to vanish exactly for CPT-invariant theories. In [63], the data from the KTeV E731 experiment [64] and the experiments on kaons [65, 66] have been used to get bounds on θ. The constraints obtained are similar to the ones coming from nuclear experiments described above. Below we report the main results.

Considering QFT on the Moyal plane, that is the standard point-wise product is deformed into (2.1), we get the following expression for the K^0–$\overline{K}^0$ mass difference at first order in $\vec{\theta}^0 \equiv (\theta^{01}, \theta^{02}, \theta^{03})$ [63]:

$$m_{K_0} - m_{\bar{K}_0} \simeq \delta_\perp \big(m_{K_0}\vec{\theta}^0\vec{P}_{in}\big)\sqrt{1 + \tan^2(\phi_{SW})}, \tag{7.12}$$

where ϕ_{SW} is called the *super-weak angle*, while $\delta_\perp$ is given in terms of the CPT violating parameter δ and ϕ_{SW}: $\delta_\perp = -\mathrm{Re}\ \delta\ \sin(\phi_{SW}) + \mathrm{Im}\ \delta\ \cos(\phi_{SW})$.

From the KTeV E731 experiment, we get for ϕ_{SW}:

$$\phi_{SW} = 43.4^\circ \pm 0.1^\circ. \tag{7.13}$$

Using the measurements of the complex and real part of δ from kaon decay experiments [65, 66] and the above value of ϕ_{SW} in (7.13), we get:

$$\delta_\perp \simeq 20.93\ \times 10^{-5}. \tag{7.14}$$

Plugging back (7.13) and (7.14) in (7.12), we can solve for $\vec{\theta}^0$ finding

$$\sqrt{|\vec{\theta}^0|} < 10^{-32}\ \mathrm{m}.$$

This corresponds to a lower bound for the energy scale associated to noncommutativity of the order of 10^{16} GeV.

We emphasis that the above bounds are obtained for "electric" noncommutativity ($\vec{\theta}^0 \neq 0$, $\theta^{ij} \equiv 0$) and not for "magnetic" noncommutativity ($\vec{\theta}^0 \equiv 0$, $\theta^{ij} \neq 0$ for some i, j).

Further details can be found in [63].

In [63], CPT measurements on the $g - 2$ difference of μ^+ and μ^- [67, 68, 69, 70] have been also used to constrain θ. The derivation is similar to the kaon case but, the mass of the muon being considerably smaller than the kaon mass, we get a much weaker bound:

$$\sqrt{\theta} < 10^{-20}\ \mathrm{m}.$$

It corresponds to a lower bound for the energy scale of 10^3 GeV.

The measurements of the $g - 2$ difference of e^+ and e^- are much more precise then the ones on muons. But still they do not give good bounds on θ, the electron being even lighter than the muon.

8   Final remarks

We can now briefly outline how to generalize our considerations on the Wick–Voros twist (3.3) to 2N-dimensions[4]. We can always choose $\hat{x}_\mu$ so that $\theta_{\mu\nu}$, now an $2N \times 2N$ skew-symmetric matrix, becomes a direct sum of N 2×2 ones. These 2×2 matrices are of the form (3.2), but different 2×2 matrices may have different factors θ. For every such 2×2 block, we have a pair of $\hat{x}$'s which can be treated as in the 2-dimensional case above. (Of course there is no twist in any block with a vanishing θ.)

---

[4]In $2N + 1$-dimensions, we can always choose $\theta_{\mu\nu}$ so that $\theta_{\mu,2N+1} = \theta_{2N+1,\mu}$=0.
